UML Profile for Enterprise Distributed Object Computing Specification

This OMG document replaces the submission (ad/2001-06-09) and the draft adopted specification (ptc/2001-12-04). It is an OMG Final Adopted Specification, which has been approved by the OMG board and technical plenaries, and is currently in the finalization phase. Comments on the content of this document are welcomed, and should be directed to issues@omg.org by July 1, 2002.

You may view the pending issues for this specification from the OMG revision issues web page http://www.omg.org/issues/; however, at the time of this writing there were no pending issues.

The FTF Recommendation and Report for this specification will be published on September 20, 2002.
UML Profile for Enterprise Distributed Object Computing Specification

FTF Final Adopted Specification
February 2002
The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

PATENT

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

NOTICE

The information contained in this document is subject to change without notice. The material in this document details an Object Management Group specification in accordance with the license and notices set forth on this page. This document does not represent a commitment to implement any portion of this specification in any company's products.

WHILE THE INFORMATION IN THIS PUBLICATION IS BELIEVED TO BE ACCURATE, THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS MATERIAL INCLUDING, BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR PARTICULAR PURPOSE OR USE. In no event shall The Object Management Group or any of the companies listed above be liable for errors contained herein or for indirect, incidental, special, consequential, reliance or cover damages, including loss of profits, revenue, data or use, incurred by any user or any third party. The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials. ISSUE REPORTING

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page http://www.omg.org, under Documents & Specifications, Report a Bug/Issue.
Contents

Preface ................................................................. xiii

1. Introduction ......................................................... 1-1
   1.1 Guide to the Specification ................................. 1-1
       1.1.1 Overall Structure of the Specification .......... 1-1
   1.2 Conformance Issues ........................................ 1-3
       1.2.1 Summary of optional versus mandatory interfaces 1-3
       1.2.2 Compliance Points .................................. 1-3
       1.2.3 Optional Compliance Points ....................... 1-4
   1.3 Proof of Concept ............................................ 1-5
       1.3.1 CBOP ................................................. 1-5
       1.3.2 Data Access Technologies ......................... 1-5
       1.3.3 DSTC ............................................... 1-6
       1.3.4 EDS ............................................... 1-6
       1.3.5 Fujitsu ............................................. 1-6
       1.3.6 IBM ............................................... 1-7
       1.3.7 Iona ............................................... 1-7
       1.3.8 Open-IT and SINTEF ............................... 1-7
       1.3.9 Sun Microsystems ................................. 1-8
       1.3.10 Unisys ........................................... 1-8
       1.3.11 ebXML ........................................... 1-8

2. EDOC Profile: Rationale and Application ....................... 2-1
   Section I - Vision
   2.1 Overview .................................................. 2-2
Contents

Section II - The EDOC Profile Elements

2.2 The Enterprise Collaboration Architecture ................. 2-3
   2.2.1 Component Collaboration Architecture ........ 2-4
   2.2.2 Entities profile .................................. 2-5
   2.2.3 Events Profile .................................... 2-6
   2.2.4 Business Process profile .......................... 2-7
   2.2.5 Relationships profile ............................... 2-7

2.3 Patterns .................................................. 2-8

2.4 Technology Specific Models and Technology Mappings . 2-10

Section III - Application of the EDOC Profile Elements

2.5 Separation of Concerns and Viewpoint Specifications .... 2-12

2.6 Enterprise Specification .................................. 2-14
   2.6.1 Concepts ............................................ 2-14
   2.6.2 EDOC Enterprise Subprofile ......................... 2-15

2.7 Computational Specification ............................... 2-16
   2.7.1 Concepts ............................................ 2-16
   2.7.2 EDOC Computational Specifications .................. 2-16
   2.7.3 Levels of ProcessComponent in a Computational Specification ........................................ 2-17

2.8 Information Specification .................................. 2-19
   2.8.1 Concepts ............................................ 2-19
   2.8.2 EDOC Information Specifications ...................... 2-20

2.9 Engineering Specification ................................ 2-20
   2.9.1 Concepts ............................................ 2-20
   2.9.2 EDOC Engineering Specifications ...................... 2-21

2.10 Technology Specification .................................. 2-21

2.11 Specification Integrity - Interviewpoint Correspondences . 2-21
   2.11.1 Computational-Enterprise Interrelationships ...... 2-21
   2.11.2 Computational-Information Interrelationships .... 2-21
   2.11.3 Computational-Engineering Interrelationships ... 2-22
   2.11.4 Engineering-Technology Interrelationships ...... 2-22

3. The Enterprise Collaboration Architecture ................. 3-1

Section I - ECA Design Rationale

3.1 Key Design Features ...................................... 3-2
   3.1.1 Recursive component composition .................. 3-3
   3.1.2 Process Specification ................................ 3-4

Section III - The Entities Profile

3.8 Introduction ............................................. 3-147
3.8.1 Normative sections .......................... 3-147
3.8.2 Relationship to other parts of ECA .............. 3-147
3.8.3 Design Concepts .............................. 3-148
3.8.4 Standard UML Facilities .................. 3-154
3.9 Entity Viewpoints ................................. 3-155
3.9.1 Information Viewpoint ....................... 3-155
3.9.2 Composition viewpoint ...................... 3-156
3.10 Entity Metamodel ................................. 3-157
3.10.1 Overview .................................. 3-157
3.10.2 Entity Package ............................... 3-158
3.11 Entity UML Profile ................................. 3-168
3.11.1 Metamodel Mapping to Profile .......... 3-169
3.11.2 Entity Package ................................ 3-169

Section IV - The Events Profile

3.12 Rationale ............................................. 3-179
3.12.1 Introduction .................................. 3-179
3.12.2 Overall design rationale .................. 3-180
3.12.3 Concepts .................................. 3-181
3.12.4 Key Concepts of event driven business and system models .................. 3-182
3.12.5 Event and Notification based Interaction Models .................. 3-185
3.12.6 Leveraging event based models ........... 3-188
3.13 Metamodel ............................................. 3-190
3.13.1 Business Process View .............. 3-190
3.13.2 Entity View ................................ 3-192
## Contents

3.13.3 Whole Event Model ...................... 3-192  
3.13.4 Publish and Subscribe Package .......... 3-194  
3.13.5 Event Package ......................... 3-199  
3.14 UML Profile ................................ 3-206  
   3.14.1 Table mapping concepts to profile elements .. 3-206  
   3.14.2 Introduction .......................... 3-207  
   3.14.3 Publish and Subscribe Package .......... 3-207  
   3.14.4 Event Package 2 ..................... 3-210  
3.15 Relationship to other ECA profiles ........ 3-215  
   3.15.1 Relationship to Business Process profile and Entities profile ................. 3-215  
   3.15.2 Relationship to ECA CCA profile ........ 3-216  
3.16 Relationship other paradigms .......... 3-217  
   3.16.1 ebXML .................................. 3-218  
3.17 Example .................................. 3-218

### Section V - The Business Process Profile

3.18 Introduction ............................... 3-220  
3.19 Metamodel .................................. 3-220  
   3.19.1 Business Process metamodel .......... 3-225  
3.20 UML Profile ................................ 3-245  
   3.20.1 Table mapping concepts to profile elements .. 3-245  
   3.20.2 Relationships ......................... 3-266  
3.21 Notation for Activity and ProcessRole .... 3-268  
3.22 Process Model Patterns ................. 3-270  
   3.22.1 Timeout ............................... 3-271  
   3.22.2 Terminate ............................. 3-272  
   3.22.3 Activity Preconditions and Activity Postconditions ......................... 3-273  
   3.22.4 Simple Loop .......................... 3-275  
   3.22.5 While and Repeat-Until Loops .......... 3-276  
   3.22.6 For Loop ............................. 3-277  
   3.22.7 Multi-Task ............................ 3-278  
3.23 Full Model ................................ 3-279

### Section VI - The Relationships Profile

3.24 Requirements .............................. 3-280  
   3.24.1 Introduction .......................... 3-280  
   3.24.2 Non-Binary Relationships .............. 3-281
Contents

3.24.3 Example: Mutually Orthogonal Non-Binary Aggregations 3-282
3.24.4 Example: Multiple Subtyping 3-285
3.24.5 Other Relationship Requirements 3-285
3.25 Using UML to Address the Requirements: An Overview 3-286
3.26 Formal Virtual Metamodel of the UML Extensions 3-286
3.26.1 Aggregations 3-287
3.26.2 Reference Relationships 3-294
3.27 Mapping the Relationships to Technical Platforms 3-298
3.27.1 Aggregations 3-298
3.27.2 Reference Relationships 3-301
3.28 Examples Using the UML Extensions 3-302
3.28.1 Example: List and Subordination 3-302
3.28.2 Example: Reference Relationships 3-304

4. The Patterns Profile 4-1

Section I - Rationale

4.1 Introduction 4-2
4.2 Pattern Principle 4-3
4.3 Notation for Patterns 4-4
4.4 Simple Pattern 4-6
4.5 Pattern Inheritance 4-6
4.6 Pattern Composition 4-7
4.7 Summary of Pattern Formats 4-8
4.8 Applying Patterns 4-8

Section II - Patterns Metamodel

4.9 EDOC::Pattern Package 4-11
4.9.1 Business Pattern Name 4-11
4.9.2 Business Pattern Package 4-12
4.9.3 Business Pattern Binding 4-13

Section III - UML Profile

4.10 Table mapping concepts to profile elements 4-14
4.11 Introduction 4-14
4.12 Pattern Package 4-15
4.12.1 BP Name 4-15
4.12.2 BP Package 4-15
### Contents

4.12.3 BP Binding ........................................ 4-17

5. Technology Specific Models .......................... 5-1

**Section I - The EJB and Java Metamodels**

5.1 Introduction ........................................ 5-1
5.2 The Java Metamodel ................................. 5-2
  5.2.1 Class Contents ................................ 5-3
  5.2.2 Polymorphism .................................. 5-8
  5.2.3 JavaType ....................................... 5-9
  5.2.4 TypeDescriptor ................................. 5-10
  5.2.5 Data Types .................................... 5-11
  5.2.6 Names .......................................... 5-12
5.3 The Enterprise JavaBeans Metamodel ............... 5-12
  5.3.1 Main ........................................... 5-13
  5.3.2 EJB ............................................ 5-18
  5.3.3 Entity Bean .................................... 5-23
  5.3.4 Assembly ....................................... 5-24
  5.3.5 EJB Implementation ............................ 5-26
  5.3.6 References to Resources ....................... 5-28
  5.3.7 Data Types .................................... 5-30
5.4 UML Profile ......................................... 5-31
  5.4.1 Java Profile ................................... 5-31
  5.4.2 EJB Profile ................................... 5-32

**Section II - Flow Composition Model**

5.5 Introduction ........................................ 5-32
5.6 FCMCore Package ................................. 5-33
  5.6.1 FCMComposition ............................... 5-34
  5.6.2 FCMComponent ................................. 5-34
  5.6.3 FCMNode ....................................... 5-35
  5.6.4 FCMConnection ................................. 5-35
  5.6.5 FCMOperation ................................. 5-35
  5.6.6 FCMParameter ................................. 5-35
  5.6.7 FCMCommand ................................... 5-35
  5.6.8 FCMFunction ................................... 5-36
  5.6.9 FCMTerminal ................................... 5-36
  5.6.10 FCMTerminalToNodeLink and FCMTerminalToTerminalLink ................................. 5-36
  5.6.11 FCMAnnotation ............................... 5-36
Contents

5.6.12 FCMSource and FCMSink ....................... 5-37
5.6.13 FCMCompositionBinding .................... 5-37
5.6.14 TDLangElement .............................. 5-37
5.6.15 FCMType .................................. 5-37
5.7 FCM Package .................................. 5-38
  5.7.1 FCMControlLink ........................... 5-39
  5.7.2 FCMDataLink ................................ 5-39
  5.7.3 FCMDecisionNode ......................... 5-39
  5.7.4 FCMConditionalControlLink ............... 5-40
  5.7.5 FCMJoinNode ................................ 5-40
  5.7.6 FCMJoinCommand ......................... 5-40
  5.7.7 FCMMappingNode .......................... 5-40
  5.7.8 FCMMappingDataLink ....................... 5-41
  5.7.9 FCMMapping ............................... 5-41
  5.7.10 FCMCondition ............................ 5-41
  5.7.11 FCMBranchNode ......................... 5-41
5.8 FCM Profile .................................. 5-41
5.9 Example ...................................... 5-42

6. UML Profile for MOF ............................. 6-1
  
  Section I - Introduction
  
  Section II - UML to MOF Mapping Table
  
  Section III - Mapping Details
  
  6.1 ModelElement ................................. 6-4
    6.1.1 Tags on UML ModelElement ............... 6-4
    6.1.2 ModelElement Property Map ............... 6-4
    6.1.3 ModelElement Constraints ................ 6-4
    6.1.4 ModelElement Limitations ................ 6-4
  6.2 Package ..................................... 6-4
    6.2.1 Tags on UML Model with Stereotype
          <<metamodel>> .................................. 6-5
    6.2.2 Model-to-Package Property Map .......... 6-5
    6.2.3 Model-to-Package Constraints ........... 6-5
    6.2.4 Model-to-Package Limitations .......... 6-5
  6.3 Import ..................................... 6-6
    6.3.1 Tags on UML ElementImport ............... 6-6
    6.3.2 ElementImport-to-Import Property Map ... 6-6
    6.3.3 ElementImport-to-Import Constraints ... 6-6
Contents

6.3.4 ElementImport-to-Import Limitations ............ 6-6
6.4 Class .................................................. 6-6
  6.4.1 Tags on UML Class .................................. 6-6
  6.4.2 Class Property Map ................................. 6-7
  6.4.3 Class Constraints .................................. 6-7
  6.4.4 Class Limitations .................................. 6-7
6.5 Attribute ............................................... 6-7
  6.5.1 Tags on UML Attribute with No Stereotype .... 6-7
  6.5.2 Attribute Property Map ............................. 6-8
  6.5.3 Attribute Constraints ............................... 6-8
  6.5.4 Attribute Limitations ............................... 6-8
6.6 Reference .............................................. 6-8
  6.6.1 Tags on UML Attribute with Stereotype
        <<reference>> ....................................... 6-9
  6.6.2 Explicit Reference Property Map .................. 6-9
  6.6.3 Implicit Reference Property Map ................. 6-9
  6.6.4 Reference Constraints ............................... 6-9
  6.6.5 Reference Limitations ............................... 6-10
6.7 Operation ............................................... 6-10
  6.7.1 Tags on UML Operation ............................... 6-10
  6.7.2 Operation Property Map ............................. 6-10
  6.7.3 Operation Constraints ............................... 6-10
  6.7.4 Operation Limitations ............................... 6-10
6.8 Parameter .............................................. 6-11
  6.8.1 Tags on UML Parameter ............................... 6-11
  6.8.2 Parameter Property Map ............................. 6-11
  6.8.3 Parameter Constraints ............................... 6-11
  6.8.4 Parameter Limitations ............................... 6-11
6.9 Exception .............................................. 6-11
  6.9.1 Tags on UML Exception ............................... 6-11
  6.9.2 Exception Property Map ............................. 6-12
  6.9.3 Exception Constraints ............................... 6-12
  6.9.4 Exception Limitations ............................... 6-12
6.10 Exception Parameter ................................... 6-12
  6.10.1 Tags on Attribute of UML Exception ............. 6-12
  6.10.2 Attribute-to-Parameter Property Map ............. 6-12
  6.10.3 Attribute-to-Parameter Constraints ............. 6-12
  6.10.4 Attribute-to-Parameter Limitations ............. 6-12
6.11 Association ........................................... 6-13
  6.11.1 Tags on UML Association ........................... 6-13

Preface

About the Object Management Group

The Object Management Group, Inc. (OMG) is an international organization supported by over 600 members, including information system vendors, software developers and users. Founded in 1989, the OMG promotes the theory and practice of object-oriented technology in software development. The organization’s charter includes the establishment of industry guidelines and object management specifications to provide a common framework for application development. Primary goals are the reusability, portability, and interoperability of object-based software in distributed, heterogeneous environments. Conformance to these specifications will make it possible to develop a heterogeneous applications environment across all major hardware platforms and operating systems.

OMG’s objectives are to foster the growth of object technology and influence its direction by establishing the Object Management Architecture (OMA). The OMA provides the conceptual infrastructure upon which all OMG specifications are based.

Intended Audience and Use

The information described in this manual is aimed at managers and software designers who want to produce applications that comply with the family of OMG standards. The benefit of compliance is, in general, to be able to produce interoperable applications that run in heterogeneous, distributed environments.

Context of OMG Modeling

The OMG is dedicated to producing a framework and specifications for commercially available object-oriented environments. The Object Management Architecture (as defined in the Object Management Architecture Guide) is the umbrella architecture for OMG specifications. The defining model for the architecture is the Reference Model,
which classifies the components, interfaces, and protocols that compose an object system. The Reference Model consists of the following components:

- **Object Request Broker**, which enables objects to transparently make and receive requests and responses in a distributed environment. It is the foundation for building applications from distributed objects and for interoperability between applications in hetero- and homogeneous environments. The architecture and specifications of the Object Request Broker are described in *CORBA: Common Object Request Broker Architecture and Specification*.

- **Object Services**, a collection of services (interfaces and objects) that support basic functions for using and implementing objects. Services are necessary to construct any distributed application and are always independent of application domains. For example, the Life Cycle Service defines conventions for creating, deleting, copying, and moving objects; it does not dictate how the objects are implemented in an application. Specifications for Object Services are contained in *CORBA Services: Common Object Services Specification*.

- **Common Facilities**, a collection of services that many applications may share, but which are not as fundamental as the Object Services. For instance, a system management or electronic mail facility could be classified as a common facility.

- **Application Objects**, which are objects specific to particular commercial products or end user systems. Application Objects correspond to the traditional notion of applications, so they are not standardized by the OMG. Instead, Application Objects constitute the uppermost layer of the Reference Model.

- **OMG Modeling**, a collection of modeling specifications that advance the state of the industry by enabling OO visual modeling tool interoperability. OMG Modeling provides a set of CORBA interfaces that can be used to define and manipulate a set of interoperable metamodels.

OMG formal documents are available from our web site in PostScript and PDF format. To obtain print-on-demand books in the documentation set or other OMG publications, contact the Object Management Group, Inc., at:

OMG Headquarters
250 First Avenue, Suite 201
Needham, MA  02494
USA

**Typographical Conventions**

The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or section headings where no distinction is necessary.

- **Helvetica bold** - OMG Interface Definition Language (OMG IDL) and syntax elements.
- **Courier bold** - Programming language elements.
- **Helvetica** - Exceptions

Terms that appear in *italics* are defined in the glossary. Italic text also represents the name of a document, specification, or other publication.

**Acknowledgments**

This specification was prepared by the following companies:

- CBOP
- Data Access Technologies
- DSTC
- EDS
- Fujitsu
- IBM
- Iona Technologies
- Open-IT
- Sun Microsystems
- Unisys

Supporting companies are:

- Adaptive
- Hitachi
- Netaccount
- SINTEF

1.1 Guide to the Specification

1.1.1 Overall Structure of the Specification

Chapter 1 introduces the specification.

Chapter 2 explains the overall rationale for the approach, and provides a framework for system specification using the EDOC Profile. It provides a detailed rationale for the modeling choices made and describes how the various elements in the specification may be used, within the viewpoint oriented framework of the Reference Model of Open Distributed Processing (RM-ODP), to model all phases of a software system’s lifecycle, including, but not limited to:

- The analysis phase when the roles played by the system’s components in the business it supports are defined and related to the business requirements.
- The design and implementation phases, when detailed specifications for the system’s components are developed.
• The maintenance phase, when, after implementation, the system's structure or behavior is modified and tuned to meet the changing business environment in which it will work.

Chapter 3 is the Enterprise Collaboration Architecture (ECA) and contains the detailed profile specifications for platform/technology independent modeling elements of the profile, specifically:
• The Component Collaboration Architecture (CCA) which details how the UML concepts of classes, collaborations and activity graphs can be used to model, at varying and mixed levels of granularity, the structure and behavior of the components that comprise a system.
• The Entities profile, which describes a set of UML extensions that may be used to model entity objects that are representations of concepts in the application problem domain and define them as composable components.
• The Events profile, which describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model event driven systems.
• The Business Processes profile, which specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model workflow-style business processes in the context of the components and entities that model the business.
• The Relationships profile, which describes the extensions to the UML core facilities to meet the need for rigorous relationship specification in general and in business modeling and software modeling in particular.

Chapter 4 is the Patterns Profile, which defines how to use UML and relevant parts of the ECA profile to express object models such as Business Function Object Patterns (BFOP) using pattern application mechanisms.

Chapter 5 provides a set of technology specific mappings. It contains Java, Enterprise JavaBeans (EJB) and Flow Composition Model (FCM) metamodels abstracted from their respective specifications:
• The EJB metamodel is intended to provide sufficient detail to support the creation assembly and deployment of Enterprise JavaBeans.
• The Java metamodel is intended to provide sufficient detail to support the EJB metamodel.
• The Flow Composition Model provides a common set of design abstractions across a variety of flow model types used in message brokering and delivery.

Chapter 6 (UML Profile for MOF) is a normative two way mapping between UML and the MOF. Although this is not called for in the RFP, it is deemed essential, since, for the profiles proposed to be understood, it has been necessary to include metamodels that explain the concepts that the profiles express.
Note: Part II of this specification, (ad/2001/08/20) is non-normative and contains supporting information in the form of the following Annexes:

- Annex A - Procurement, Buyer/Seller example
- Annex B - Meeting Room example
- Annex C - Hospital example
- Annex D - Examples of Patterns
- Annex E - Technology mappings from EDOC to Distributed Component and Message Flow Platform Specific Models

In addition, XMI and DTD data files for the metamodels in the EJB/Java/FCM profiles are included in the zip file containing this Part II of the specification, in the folder named “XMI and DTDs.”

1.2 Conformance Issues

1.2.1 Summary of optional versus mandatory interfaces

For a modeling tool to claim compliance to the EDOC specification it must implement at least one of the mandatory compliance points in Section 1.2.2.1, and state the name of the compliance point(s). The mandatory compliance points are all variations on the ability to model or interchange designs using the Enterprise Component Architecture (ECA), which forms the core of EDOC.

There are a number of other normative profiles and metamodels contained within this specification, and these are given named optional compliance points in Section 1.2.3, “Optional Compliance Points,” on page 1-4.

1.2.2 Compliance Points

1.2.2.1 Mandatory Compliance Points

At least one of the following compliance points must be implemented for a tool or model to claim compliance with the EDOC specification.

<table>
<thead>
<tr>

1.2.3 Optional Compliance Points

The specification has the following optional compliance points:

**Patterns Profile**
Any tool that implements the Profile mechanisms defined in UML 1.4 (ad/01-02-13), and which is populated with stereotypes, tagged values and constraints defined in the EDOC::Pattern «profile» Package, and all of its sub-packages.

**Patterns Model**
Or any tool that implements the semantics of the MOF metamodel EDOC::Pattern package (Chapter 4), and allows access to patterns generated either by generated MOF 1.3 (formal/00-04-03) IDL interfaces or via XML documents produced via the application of XMI 1.1 (formal/00-11-02) to the metamodel.
Java Model
Use of the normative Java metamodel (see Section 5.2, “The Java Metamodel,” on page 5-2) by instantiation, code generation, invocation, or serialization as defined by the MOF 1.3 (formal/00-04-03) and XMI 1.1 (formal/00-11-02) specifications.

EJB Model
Use of the normative EJB metamodel (see Section 5.3, “The Enterprise JavaBeans Metamodel,” on page 5-12) by instantiation, code generation, invocation, or serialization as defined by the MOF 1.3 (formal/00-04-03) and XMI 1.1 (formal/00-11-02) specifications.

FCM Model
Use of the normative FCM metamodel (see Chapter 5, “Section II - Flow Composition Model”) by instantiation, code generation, invocation, or serialization as defined by the MOF 1.3 (formal/00-04-03) and XMI 1.1 (formal/00-11-02) specifications.

UML Profile for MOF
Any tool that implements the Profile mechanisms defined in UML 1.4 (ad/01-02-13), and which is populated with stereotypes, tagged values and constraints defined in the uml2mof «profile» Package (Chapter 6).

CCA Notation

1.3 Proof of Concept
This specification is a practical approach to the need for specifying EDOC systems, based on the following real world experience of the companies concerned:

1.3.1 CBOP
CBOP is a consortium in Japan, promoting the reuse and the sharing of business domain models and software components. The submission of the pattern mechanism to the UML profile for EDOC RFP was based on the CBOP standards that are focused on the normalization of business object patterns for modeling. Current work of CBOP is, *inter alia*, concerned with the development of UML tools that enable the application of patterns in object modeling with UML. The EDOC standard will be taken into account in these tools as well as the CBOP standards.

1.3.2 Data Access Technologies
The CCA profile (see Chapter 3, “Section II - The Component Collaboration Architecture”) is based on product development done by Data Access Technologies under a cooperative agreement with the National Institute of Technologies - Advanced Technology Program. The basis for CCA has been proven in two related works - one as a distributed user interface toolkit for Enterprise Java Beans and more recently as the
basis for "Component X Studio" which provides drag-and-drop assembly of server-side application components. Component-X Studio is has been released as a product. Portions of this same model have also been incorporated into ebXML for it's specification schema, giving CCA an XML based technology mapping. Finally, portions of CCA and the related entity model derive from standards, development and consulting work done in relation to the "Business Object Component Architecture" which, while never standardized has proven to be a solid foundation for modeling and implementing a systems information viewpoint. In all cases of the above works, model based development has been used throughout the lifecycle, from design to deployment - proving the sufficiency of the base models to drive execution.

1.3.3 DSTC

DSTC has used its dMOF product to develop a MOF repository and Human Usable Textual Notation I/O tools which support modeling of Business Processes conforming to the metamodel in Chapter 3, “Section V - The Business Process Profile”). Significant Business Process models have been created using these generated tools, and mapped using XSLT into XML workflow process definitions, which execute on the DSTC's Breeze workflow engine. dMOF is a commercial product installed at many customer sites world-wide, and Breeze is in development and is currently being beta-tested by four DSTC partner organizations.

In addition the dMOF tool has been used to validate the MOF conformance of all the meta-models in Chapter 3. XMI documents containing these meta-models will be submitted as separate convenience documents.

1.3.4 EDS

EDS developed the Enterprise Business Object Facility (EBOF) product in conjunction with work on the Business Object Facility specification. This product serves as a proof of concept for important aspects of this submission. It incorporated UML models as the basis for generating executable, distributed, CORBA applications. This involved consideration of transactions, persistence, management of relationships, operations on extents, performance optimization and many other factors. This product was sold to a major software vendor.

1.3.5 Fujitsu

This submission is based in part upon Fujitsu's system analysis and design methodology, "Application Architecture/Business Rule Modeling". The methodology is built into Fujitsu's product, "Application Architecture / Business Rule Modeler - AA/BRMODELER", which has been used for the development of many mission critical business systems. Although applied mainly to the development of COBOL applications, the methodology includes object-oriented characteristics. In this submission, the elements of the methodology and its related product are represented as UML elements and extensions. In the methodology, the specification of business rules is of special concern. The business rules are separated in types and attributed to objects corresponding to the types. These rules are represented in a formal grammar, and they
are compiled into executable programs by using AA/BRMODELER. AA/BRMODELER has sold approximately 5000 sets in Japan since it was developed in 1994. It has been applied to approximately 300 projects, some of scale greater than 7,000 person-months.

1.3.6 IBM

IBM has extensive experience in enterprise architectures, Java, Enterprise Java Beans, CORBA, UML, MOF, and metadata. The WebSphere, MQ, and VisualAge product lines provide sophisticated analysis, design, deployment, and execution functionality embodying all of the key representative technologies.

1.3.7 Iona

The Relationships Profile is based on many years of modeling experience in industry and in the development of related products and standards. It uses ISO's General Relationship Model and the work of Haim Kilov and James Ross in their book "Information Modeling", which is based on long-term modeling experience in areas such as telecommunications, finance, insurance, document management, and business process change.

The Process Profile incorporates Iona experience modeling enterprise processes with customers from use case descriptions, business models, and other IT system requirements information. It is also based on experience developing process definition and management products for environments ranging from concurrent engineering to document processing.

1.3.8 Open-IT and SINTEF

The profile incorporates results and experience from the UML profile and associated lexical language that was developed in the European Union funded OBOE project. As part of this project supporting tools were developed and the technology was applied at a user site. A full description of the project is available at [7]. (see Appendix A).

The ODP concepts have been applied for the development of the OMG Finance domain General Ledgers specification in the COMPASS project, and a mapping framework for Microsoft COM has been developed by Netaccount (formerly Economica). More information on this is available at [6] (see Appendix A).

The ODP concepts have also been applied in the domain of geographic information systems. The DISGIS project has demonstrated the usefulness of the separation of concerns in terms of the 5 viewpoints defined by the RM-ODP, and developed an interoperability framework based on this (See [5], Appendix A). The use of the ODP viewpoints have also been found useful in the context of geographic information system standardization in ISO/TC211 (See [8], Appendix A) and the Open Geodata Consortium (See [9], Appendix A).
The enterprise specification concepts have been derived from work for the UK Ministry of Defence and Eurocontrol together with participation in the development of the ODP – Enterprise Language standard (See [4], Appendix A).

1.3.9 Sun Microsystems

Sun Microsystems' internal IT group has successfully implemented large scale Enterprise Integration using a conceptual meta-model close to that defined in the Events profile (Chapter 3, “Section IV - The Events Profile”), covering business process, entity, and event architecture. While this has not been using UML, the work modeled the enterprise and the interaction between system components based on an enterprise business object/event information model. Business objects and events have been modeled in a Sun IT internal language, SDDL, a self describing data language, the syntax of which is equivalent to the modeling framework proposed here.

This implementation is successful, and by a rough estimate 50% of Sun’s key applications participate in event driven processes, and in total about a million event notifications are sent among these applications every day.

1.3.10 Unisys

Unisys has extensive experience in enterprise architectures, commercial metadata repositories, metadata interchange, Java, Enterprise Java Beans, CORBA, COM+, UML, and MOF. Unisys products provide extensive and distributed metadata management services. Unisys has designed numerous metamodels using UML, and has deployed numerous metamodels using MOF, including metamodels of Java, CORBA IDL, UML, and CWM.

1.3.11 ebXML

The ebXML Business Process Specification Schema (BPSS), which was adopted as a specification on May 11th 2001, is aligned with and validates the Component Collaboration Architecture (CCA). This alignment was demonstrated as part of the ebXML “proof of concept” on the same day. This alignment validates the use of CCA concepts to express Business-to-Business processes in a precise (executable) manner. The United Nations and Oasis jointly sponsor EbXML.

Section I - Vision

2.1 Overview

The vision of the EDOC Profile is to simplify the development of component based EDOC systems by means of a modeling framework, based on UML 1.4 and conforming to the OMG Model Driven Architecture (see [30] in Appendix A), that provides:

- A platform independent, recursive collaboration based modeling approach that can be used at different levels of granularity and different degrees of coupling, for both business and systems modeling and encompasses:
  - A loosely coupled, re-useable business collaboration architecture that can be leveraged by business-to-business (b2b) and business-to-customer (b2c) applications, as well as for enterprise application integration.
  - A business component architecture that provides interoperable business components and services, re-use and composable of components and re-use of designs and patterns, while being independent of choice of technology (e.g., component models), independent of choice of middleware (e.g., message services) and independent of choice of paradigms (e.g., synchronous or asynchronous interactions).

- Modeling concepts for describing clearly the business processes and associated rules that the systems support, the application structure and use of infrastructure services, and the breakdown of the system into configurable components.

- An architectural approach that allows the integration of “process models” and “information models.”

- A development approach that allows two-way traceability between the specification, implementation and operation of Enterprise computing systems and the business functions that they are designed to support.

- Support for system evolution and the specification of collaboration between systems.

- A notation that is accessible and coherent.

The vision addresses key business needs by enabling the development of tools that support:

- Business collaborations as a central concern – covering alliances, outsourcing, supply chains, and internet commerce, and dealing with relationships that are in constant flux where what is inside the enterprise today is outside tomorrow, and vice versa.

- Process engineering by assembling services – so that basic business functions can remain relatively constant while who performs them and in what sequence changes, and services themselves can become proactive.

- The ability for parts of the enterprise to react quickly and reliably to change through:
Shorter development time and improved quality of applications meeting market needs, improved interoperability between systems and support for distributed computing.

Reduced lead time and improved quality resulting from the ability to generate a substantial portion of application code.

More robust specification by removing ambiguity and enabling more rigorous analysis of designs.

A new marketplace for interoperable collaboration based infrastructures and business components.

The EDOC Profile provides this modeling framework by defining:

- A set of Profile Elements comprising:
  - A technology independent profile, the Enterprise Collaboration Architecture (ECA) allowing the definition of Platform Independent Models as defined by the MDA.
  - A Patterns Profile that can be applied in specifications that use the ECA.
  - A set of Technology specific Models allowing the definition of Platform Dependent Models as defined by the MDA.

- A structure for the application of the Profile Elements in the specification of EDOC systems that conforms to the MDA.

This remainder of this chapter:

- provides an overview of the Profile Elements (Section II), and
- defines how the Profile Elements are applied in the specification of an EDOC system (Section III).

The ECA is fully defined in Chapter 3, the Patterns Profile in Chapter 4, and the Technology specific Models in Chapter 5. Non-normative mappings from the ECA to the Technology specific Models defined in Chapter 5 are described in Section II.

Section II - The EDOC Profile Elements

2.2 The Enterprise Collaboration Architecture

The Enterprise Collaboration Architecture (ECA) comprises a set of five UML profiles:

- The Component Collaboration Architecture (CCA) which details how the UML concepts of classes, collaborations and activity graphs can be used to model, at varying and mixed levels of granularity, the structure and behavior of the components that comprise a system.

- The Entities profile, which describes a set of UML extensions that may be used to model entity objects that are representations of concepts in the application problem domain and define them as composable components.
• The Events profile, which describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model event driven systems.

• The Business Process profile, which specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model system behavior in the context of the business it supports.

• The Relationships profile, which describes the extensions to the UML core facilities to meet the need for rigorous relationship specification in general and in business modeling and software modeling in particular.

Each profile consists of a set of UML extensions that represent concepts needed to model specific aspects of EDOC systems. The concepts are described in terms of UML profiles.

The semantics of each profile (except for the Relationships Profile) are also expressed in a UML-independent MOF metamodel.

The ECA profiles are technology independent and are used together to define platform independent models of EDOC systems in conformance with the MDA. In particular, they enable the modeling of the concepts that until now have had to be specified programmatically in terms of the use of services such as events/notifications, support for relationships and persistence.

2.2.1 Component Collaboration Architecture

The Component Collaboration Architecture (CCA) details how the UML concepts of classes, collaborations and activity graphs can be used to model, at varying and mixed levels of granularity, the structure and behavior of the components that comprise a system. It defines an architecture of recursive decomposition and assembly of parts, which may be applied to many domains.

The term component is used here to designate a logical concept - a “part,” something that can be incorporated in a logical composition. It is referred to in the CCA as a Process Component. In many cases Process Components will correspond, and have a mapping, to physical components and/or deployment units in a particular technology.

A Process Component is a processing component: it collaborates with other Process Components within a CCA Composition, interacting with them through Ports, where Ports are an abstraction of interfaces of various types (e.g., synchronous, asynchronous). Process Components can be used to build other Process Components or to implement roles in a process – such as a vendor in a buy-sell process.

Process Components collaborate at a given level of specification collaborate and are themselves decomposed at the next lower level of specification. Thus the concepts of Process Component and Composition are interdependent.
The recursive decomposition of Process Components utilizes two constructs in parallel: Composition (using UML Collaboration) to show what Process Components must be assembled and how they are put together to achieve the goal, and Choreography (using UML Activity Graph) to show the flow of activities to achieve a goal. The CCA integrates these concepts of “what” and “when” at each level.

Since CCA, by its very nature, may be applied at many levels and the specification requirements at these various levels are not exactly the same, the CCA can be further specialized with profiles for each level using the same profile mechanisms. Thus Process Components exposed on the Internet will require features of security and distribution, while more local Process Components will only require a way to communicate, and there may be requirements for Process Components for specific purposes such as business-2-business e-commerce, enterprise application integration, distributed objects, real-time etc.

It is specifically intended that different kinds and granularities of Process Components at different levels will be joined by the recursive nature of the CCA. Thus Process Components describing a worldwide B2B business process can decompose into application level Process Components integrated across the enterprise and these can decompose into program level Process Components within a single system. However, this capability for recursive decomposition is not always required. Any Process Component may be implemented directly in the technology of choice without requiring decomposition into other Process Components.

2.2.2 Entities profile

The Entities profile describes a set of UML extensions that may be used to model entity objects that are representations of concepts in the application problem domain and define them as composable components.

The goal is to define the entities with their attributes, relationships, operations, constraints and dependencies at a technology-independent level as components within system modeled using the CCA. The component determines the unit of distribution and interfaces that must be complemented by other components. The profile includes declarative elements for placing constraints on the profile and for rules that will propagate the effects of changes and events.

The Entities profile is used with the Events and Business Process profiles to allow definition of the logic of automated business processes and of events that may be exchanged to achieve more loosely coupled integration. These three profiles together support the design of an EDOC system on the foundation provided by the CCA.

The Entities profile is used to define a representation of the business and operations that effect changes in state of the business model. Business processes modeled using the Events profile and the Business Process profile operate on this model where the process flow determines when operations should occur as a result of inputs from other systems, the occurrence of business events or the actions of human participants.
2.2.3 Events Profile

The Events profile describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model event driven systems.

An event driven system is a system in which actions result from business events. Whenever a business event happens anywhere in the enterprise, some person or thing, somewhere, may react to it by taking some action. Business rules determine what event leads to what action. Usually the action is a business activity that changes the state of one or more business entities. Any state change to a business entity may constitute a new business event, to which, in turn, some other person or thing, somewhere else, may react by taking some action. The purpose of the Event Profile is to define the use of the concepts in the CCA, Entity and Event profiles, and to extend them in order to support the design of event-driven business systems.

The main concepts in event driven business models are the business entity, business event, business process, business activity and business rule. So the basic building blocks are the business process and the business entity. The two are ‘wired together’ by a flow of actions from process to entity, and by a flow of events from entity to process. In a component framework, therefore, business processes have event inflow and action outflow, and entities have action inflow and event outflow.

This means that CCA business process components and CCA business entity components can be created by modeling:

- A business process as a set of rules of the type notification/condition/activity (This is the event-driven equivalent of the commonly known event/condition/action rule).
- A business entity as set of operation/state/event causalities.

The connection from business process to business entity is a configurable mapping of activity to operation.

The connection from business entity to business process is a configurable set of subscriptions.

With these building blocks it is possible to model a number of event-based interactions. Furthermore, by reconfiguring the activity to operation mapping and/or the subscriptions, it is possible to re-engineer the business process and its execution in the system.

However, neither the business world, nor the computing world applies only one paradigm to their problem space. Businesses use a combination of loosely coupled and tightly coupled processes and computing solutions deploy a combination of loosely coupled and tightly coupled styles of communication and interaction between distributed components. Consequently, while the Events profile is defined to support the event-driven flavor of loosely coupled business and systems models, it allows such models to co-habit with more tightly coupled models.
2.2.4 Business Process profile

The Business Process profile specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model system behavior in the context of the business it supports.

The Business Process profile provides modeling concepts that allow the description of business processes in terms of a composition of business activities, selection criteria for the entities that carry out these activities, and their communication and coordination. In particular, the Business Process profile provides the ability to express:

- Complex dependencies between individual business tasks (i.e., logical units of work) constituting a business process, as well as rich concurrency semantics.
- Representation of several business tasks at one level of abstraction as a single business task at a higher level of abstraction and precisely defining relationships between such tasks, covering activation and termination semantics for these tasks.
- Representation of iteration in business tasks.
- Various time expressions, such as duration of a task and support for expression of deadlines.
- Support for the detection of unexpected occurrences while performing business tasks that need to be acted upon, i.e., exceptional situations.
- Associations between the specifications of business tasks and business roles that perform these tasks and also those roles that are needed for task execution.
- Initiation of specific tasks in response to the occurrence of business events.
- The exposure of actions that take place during a business process as business events.

2.2.5 Relationships profile

The Relationships profile describes the extensions to the UML core facilities to meet the need for rigorous relationship specification in general and in business modeling and software modeling in particular.

Relationships are fundamental to behavior because they are the paths over which actions occur, therefore clear, concise and rigorous specification of relationship semantics is of utmost importance. Furthermore, it should be noted that multiplicities are not the most important or most interesting properties of relationships. Property determinations are much more important for the semantics of a relationship, and distinguish among different kinds of relationships. The fragments of relationship invariants about property determination represent an essential fragment of those elusive “business rules” that are the backbone of a good specification and that should never be only “in the code.”

At the same time, it is very desirable to discover and specify – rather than reinvent – those kinds of relationships that are encountered in all specifications, so that reuse at the specification level becomes possible. Such generic relationships extend the set of reusable constructs that already exist in UML.
The Relationships profile defines generic relationships that provide concepts and constructs that permit UML to be used for specification of businesses and systems in a more rigorous manner than (and without restrictions currently imposed by) the base UML 1.4. Generic relationships provide for explicit specification of relationship semantics in class diagrams using invariants, in accordance with UML 1.4 Section 2.3.2: “The static semantics ... are defined as a set of invariants of an instance of the [association].... These invariants have to be satisfied for the construct to be meaningful.”

The approach presented is extensible, and if it appears that in a particular business (or a set of applications) additional generic relationships are needed and useful, then they may be precisely and explicitly defined and added in a manner similar to the definitions provided here.

The profile also provides advice for choosing and using a subset of UML for business modeling such a that the business models represented in terms of this subset will be readable and understandable by all stakeholders, specifically, business subject matter experts, analysts, and developers (as well as managers). The generic relationships described here are among the most important constructs of this subset.

### 2.3 Patterns

A key element of the EDOC Profile design rationale is the ability to exploit the capability of patterns to capture modeling know-how or techniques and help developers to maintain efficiency and consistency in products. Patterns allow standard models to be reused to build good object models for EDOC systems.

Many approaches to the use of patterns have been proposed, for example “Design Pattern” proposed by E.Gamma et.al (see [28] in Appendix A), “Analysis Patterns” proposed by M. Fowler [27] or “Catalysis Approach” proposed by D. D’Souza [26]. In its use of patterns the EDOC Profile focuses on improving sharability and reusability of object models rather than on assisting modeling efforts by illustrating good modeling techniques.

EDOC Patterns improve the sharability and reusability of models, by supporting the following features:

- Models are made consistent with predefined normative modeling constructs, not only with modeling manners and notations.
- Modeling constructs for common atomic objects, such as, Date, Currency, Country-code are predefined.
- Common aggregated objects, such as Customer, Company, or Order, which represent business entities, are predefined as normative modeling constructs, using normative atomic objects.
- Business concepts, such as Trade, Invoice, or Settlement, which are typically represented as relationships among objects, are defined as aggregations of the common elementary aggregated objects or simple objects, and are predefined as normative modeling constructs.
Aggregations that can be predefined using the more basic and elementary patterns as base, are defined as object patterns.

Patterns can represent business concepts where they provide for aggregation of more elementary patterns, thus aggregation or composition mechanisms are provided in patterns.

Business rules that govern a business concept are represented with a pattern with encapsulated constraints and a mechanism for constraint inheritance among patterns is provided.

A pattern is a set of types that can be instantiated to create an object model. Making a pattern from a set of object models requires identifying and defining the common types among those object models as their metamodel as in the ECA. Identifying and specifying many reusable business object patterns enables quick and high quality model development by selecting appropriate patterns to use in the project as a template.

The Patterns profile defines a standard means, Business Function Object Patterns (BFOP), for expressing object models using the UML package notation, together with the mechanisms for applying patterns that are required to describe models.

BFOP is a set of object patterns laid out in a hierarchical multi-layer structure, the Basic, Unit, Basic Model, Product (application systems) and Option layers. For example, Figure 2-1 illustrates how “Sales/Purchase Pattern” is composed from “Sales Order & Purchase Order Pattern”, “Closing Pattern” and so on. The UML parameterized collaboration mechanism is used to materialize the pattern integration.

One of the major benefits of using this multi-layered structure is that it enables reuse (inheritance) of the constraints that have been defined and encapsulated in patterns in the layers. It provides a normalized way to define constraints and is effective in maintaining consistency within the object model.

The concepts of Business Pattern Package (defining a pattern) and Business Pattern Binding (applying a pattern) have the features of pattern inheritance and pattern composition. This capability is useful for expressing patterns that include the objects constructed by recursive component composition as defined by the ECA.

The Patterns Profile defines three basic forms of pattern:

- A simple pattern, which is a pattern consisting of minimal elements needed to form a pattern.
- An inherited pattern, which is a pattern defined by inheriting from another pattern.
- A composite pattern, which is a pattern defined as a result of combining more than two patterns: the composite pattern concept is an extension of the inherited pattern.

Using the above three basic forms of pattern as the base, notations for expressing patterns and their metamodel are defined.

The instantiation of a composite pattern in a hierarchical structure becomes possible by resolving pattern inheritance and collaboration by performing "unfold." When composite patterns are granular enough to include implementation details, it is possible to use them to describe a component concept such as that defined in the CCA, each
pattern package can be implemented with real components instead of unfolding it into a components pattern. In short, the proposed pattern concept and mechanism can be applied to the components based development that is required for EDOC systems.

The Patterns profile also includes standard models from the ECA such as Business Entities, Business Processes, Business Events and Business Rules, together with a set of common and reusable patterns of relationship properties that occur in business modeling.

The profile does not define any new metamodel elements. The pattern notation uses currently available metamodel elements and patterns are described using the UML pattern notation.

![Figure 1: An Example of BFOP Pattern Hierarchy](image)

**Figure 2-1** An Example of BFOP Pattern Hierarchy

### 2.4 Technology Specific Models and Technology Mappings

The focus of the ECA is on enterprise, computational and information specifications for a platform independent model of an EDOC system. These are transformed further to engineering and technology specifications for platform specific models using technology concepts from an appropriate Technology Specific Model.

Neither the business world, nor the computing world, applies only one paradigm to their problem space. Businesses use a combination of loosely coupled and tightly coupled processes, and computing solutions to deploy a combination of loosely coupled and tightly coupled styles of communication and interaction between distributed components.
An ECA based business process can be defined as event driven for some of its steps and workflow or request/response driven for others. Likewise, distributed components in the ECA can be configured to communicate with each other in a mixture of event-driven publish-and-subscribe, asynchronous peer-to-peer, and client-server remote invocation styles.

The EDOC Profile anticipates three levels of component coupling: linked, tightly coupled and loosely coupled.

Linked coupling refers to components that are co-located in the same address space. These components interact with each other directly, without communicating over a network. As such, they can interact without being identifiable over the network. Messaging will generally be synchronous, within the scope of a single transaction.

Tightly coupled components are distributed across multiple servers. These components will also interact with synchronous messaging, but messaging will occur over a network. While some messaging between the components may be asynchronous for performance and recoverability considerations, components are tightly coupled if any interactions between them are synchronous.

Loosely coupled components are distributed and only communicate asynchronously, through a messaging infrastructure. Communication is through messages and events. A message or event is issued in the scope of one transaction and accepted by one or more recipients in independent transactions. Messages and events are stored and forwarded. A message is communicated with a defined recipient, and an event is a communicated (published) with self-declaring recipients (subscribers) unknown to the publisher.

The level of coupling between components has important performance and system flexibility implications. Generally, components should be designed in a level-of-coupling hierarchy so that components that are linked are within components that are tightly coupled, and tightly coupled components are then loosely coupled with each other. This coupling hierarchy should be reflected in the network accessibility property of components and the synchronous vs. asynchronous property of their ports.

With a consistent mapping to a particular technology, implementations of independently developed specifications should be operationally interoperable. Furthermore, components implemented with different technologies should be operationally interoperable if the technology mappings are consistent with the transformations provided by bridges between the technologies.

ECA based specifications can be mapped down to various technology choices, and in particular both container-managed components and message-based services. Two Technology Specific Models are defined as part of the EDOC Profile, for Enterprise Java Beans and Java enterprise computing architectures, and for the Flow Composition Model (FCM).

The EJB metamodel captures the concepts that will be used to design an Enterprise JavaBean-based application down to the Java implementation classes. The metamodel includes the assembly and deployment descriptor.

FCM is a general-purpose model that supports creating flow compositions of components and defining behaviors of those compositions using wiring diagrams. It provides a common set of technology abstractions across a variety of flow model types.
used in message brokering. FCM is closely tied to MQ-Series but it has more general applicability and is positioned as a layer of abstraction just above middleware technology, in contrast to the ECA Processes profile which is intended technology neutral and intended for use in an analysis level model.

Normative mappings from ECA to these models is the subject of future RFPs. Proof of concept mappings are given in Section III.

Section III - Application of the EDOC Profile Elements

2.5 Separation of Concerns and Viewpoint Specifications

The RFP states that:

“Successful implementation of an enterprise computing system requires the operation of the system to be directly related to the business processes it supports. A good object-oriented model for an enterprise computing system must therefore provide a clear connection back to the business processes and business domain that are the basis for the requirements of the system. However, this model must also be carried forward into an effective implementation architecture for the system. This is not trivial because of the demanding nature of the target enterprise distributed computing environment.”

This is reflected in the vision for this EDOC profile to provide:

• A development approach that allows two-way traceability between the specification, implementation and operation of Enterprise computing systems and the business functions that they are designed to support.

• In order to clearly and coherently address these requirements, the specification of an EDOC system must be structured to address a number of distinct sets of concerns:
  • The behavior of the system, in the context of the business for which it is implemented (i.e., its roles in some enterprise that is greater than it itself), has to be specified in a way that can be traceably linked to its design.
  • The structure of the application processing carried out by the system has to be defined in terms of configurations of objects and the interactions between them.
  • The semantics of the application processing carried out by the system have to be expressed in a way that can be traceably linked from its roles through to the functions the system provides.
  • The infrastructure of the system has to be defined in terms of the use of object services to support the application processing structure.

1. RFP p19 under the heading of “Enterprise Computing Systems”
The qualitative aspects of the system (e.g., performance and reliability objectives) have to be defined together with the hardware and software products that realize the system. These determine the physical configuration of application processing and supporting services across available resources, and how the system is managed.

This is the problem addressed by the Reference Model of Open Distributed Processing (RM-ODP) (see [1], [2], [3] Appendix A) and this specification uses as the conceptual framework for an EDOC system specification the concept of viewpoints defined in the RM-ODP. It partitions a system specification into five viewpoint specifications, namely the

- enterprise specification,
- computational specification,
- information specification,
- engineering specification, and
- technology specification.

The set of linked specifications, taken together, ensure that the system can be implemented and operated in such a way that its behavior will meet the business needs of its owners, and, furthermore, that its owners will understand the constraints on their business that operation of the system will impose.

This section explains how the concepts defined by in the EDOC Profile can be used to develop a full set of viewpoint specifications for an EDOC system and how specification integrity across the various viewpoint specifications can be ensured. In summary (Figure 2-2):

- The CCA, the Events profile, the Entities profile the Processes profile and the Relationships profile from the ECA are used, with relevant Patterns, to produce an enterprise specification (Enterprise viewpoint).
- The CCA, the Entities profile and the Events profile from the ECA are used, with relevant Patterns, to produce a computational specification (Computational viewpoint).
- The Entities profile and Relationships profile from the ECA are used, with relevant Patterns, to produce an information specification (Information viewpoint).
- A technology abstraction model such as the Flow Composition Model (FCM), with relevant Patterns, is used to produce an engineering specification (Engineering viewpoint).
- The mappings to various technologies, in particular, to J2EE with EJB, to CORBA 3 with CCM and to MS DNA/.NET with DCOM, are used to produce technology specifications (Technology viewpoint).
The overall structure of the EDOC Profile in the context of the ISO RM-ODP viewpoints is illustrated in Figure 2-2.

2.6 Enterprise Specification

2.6.1 Concepts

The enterprise specification of an EDOC system provides the essential traceability between the system design and the business processes and the business domain that are the basis for the requirement for the system.

The basis of the enterprise specification is provided by the concepts of the ODP enterprise language (modeled using the ECA elements). These concepts are defined in Appendix A - [4].

An enterprise specification models the structure and behavior of the system in the context of the business organization of which it forms a part in the following terms:
- the business processes supported by the system,
- steps in those processes and relationships between steps,
- business rules (policies) that apply to the steps,
- artifacts acted on by each step,
- enterprise objects representing the business entities involved,
- the roles that they fulfil in supporting the business processes, and
- the relationships between roles (including interaction relationships) where roles identify responsibility for steps in the business processes.

An EDOC system or each component of that system is modeled as an enterprise object and is assigned a role or roles in the community: hence, it is associated with specific parts of one or more processes. These roles identify the parts of the business processes for which the system is responsible and the artifacts that are involved. Such artifacts and resources represent the information held and acted upon by the system.

The central concept of any enterprise specification is that of a **community** that models a collection of entities interacting to achieve some purpose, which is defined by the **objective** of the community concerned. Each community is modeled as a configuration of **enterprise objects in roles**. The EDOC system of concern (or the components of that system) is modeled as one or more of the enterprise objects that are the members of the community.

The **behavior** of the members of the community is identified by the **roles** they fulfil, and is defined in terms of a set of **actions**, each of which may also be modeled as a **step** of one or more **processes**. Each process is designed to achieve the objective of the community.

Depending upon what it models, an enterprise object may be further refined as a community in a process of recursive decomposition.

**Policies** (business rules) may be associated with any other enterprise language concept and may be expressed in the form of constraints on any concept, or relationship between two concepts.

### 2.6.2 EDOC Enterprise Subprofile

The EDOC enterprise specification makes use of the CCA for the role-based definition of the enterprise structure, where:

- Communities are modeled as Composed Components with associated Composition and Choreography definitions.
- Enterprise objects are modeled as ProcessComponents.
- The interactions in which enterprise objects can participate are defined by Ports and the associated Protocols.

It makes use of the Processes profile for the process-based definition of the enterprise structure.
It makes use of the Event profile for the definition of event driven enterprise structures.

It makes use of the Entities profile for the definition of entities and rules. Artifacts, performers and responsible parties, which are the subject of the interactions, are modeled as entities.

It makes use of the Relationships profile for rigorous specification of relationships.

2.7 Computational Specification

2.7.1 Concepts

The computational specification describes the implementation of the EDOC system (or components that comprise that system) in order to carry out the processing required by the system roles in the enterprise specification. It does this in terms of functional decomposition of the system into computational objects that interact at interfaces, and thereby enables distribution. It defines:

- Computational objects that play some functional role in the system and which can be described in terms of provided interfaces and used interfaces: a set of computational objects will correspond to the implementation of roles of the system in enterprise processes, and associated enterprise events and business rules.

- The interfaces at which the computational objects interact: this includes different types of interfaces and also describes data involved in computational interactions corresponding to the information objects in the information specification.

- The collaboration structures among a set of computational objects.

The computational viewpoint is closely related to the enterprise viewpoint in that the computational objects represent a functional mapping of enterprise concepts like business processes, rules, events etc. where these relate to the roles of the system in the enterprise specification. Ways of ensuring consistency (conformance/reference points) between enterprise and computational specifications should be supported (consistency statements for corresponding conformance/reference points in the two viewpoint specifications).

The EDOC computational specification concepts are based on the RM-ODP Part 3 Clause 7 (see Appendix A [3]).

2.7.2 EDOC Computational Specifications

An EDOC computational specification makes use of the CCA for the basic definition of the computational structure, where:

- Computational objects are modeled as ProcessComponents.

- The interfaces at which computational objects interact are modeled by Ports.

- Collaboration structures among a set of computational objects are modeled by Compositions with associated Choreographies.
It makes use of the Entities Model for the definition of entity components, where entity components correspond to entities in the information specification.

It makes use of the Events Model for the definition of event driven computational structures.

### 2.7.3 Levels of ProcessComponent in a Computational Specification

An EDOC computational specification can specify ProcessComponents at a number of different levels. These levels correspond to four general categories of ProcessComponent:

- E-Business Components
- Application Components
- Distributed Components
- Program Components

#### 2.7.3.1 E-Business Components

E-Business Components are used as the integration point between enterprises, enterprises and customers or somewhat independent parts of a large enterprise (such as an acquired division). Interfaces to E-Business Components will frequently be directly accessible on the Internet as part of a web portal.

The E-Business Component has the potential to spawn new forms of business and new ways for business to work together.

E-Business Components integrate business entities that may share no common computing management or infrastructure. Interactions between E-Business components must be very loosely coupled and are always asynchronous. No assumptions of shared resources may be made between the parties, and the internals of the E-Business components will frequently be changed without informing other parties.

#### 2.7.3.2 Application Components

Application Components represent new and legacy applications within an enterprise. Application Components are used to integrate applications (EAI) and create new applications, frequently to facilitate E-Business Components.

Application Components represent large-grain functional units. Each Application Component may be implemented in different technologies for different parts of the enterprise. Integrating Application Components facilitates enterprise-wide business processes and efficiencies.

Individual Application Components may be individually managed, but the integration falls under common management that may impose standards for interoperability and security.
Application Components use a wide variety of integration techniques including messaging, events, Internet exchanges and object or procedural RPC. Application Components are frequently wrapped legacy systems.

2.7.3.3 Distributed Components

Distributed Components are functional parts of distributed applications. These components are generally integrated within a common middleware infrastructure such as EJB, CORBA Components or DCOM. Distributed components have well defined interfaces and share common services and resources within an application.

Distributed Components provide for world-wide applications that can use a variety of technologies. Most distributed component interactions are synchronous.

2.7.3.4 Program Components

Program Components act within a single process to facilitate a program or larger grain component. Program Components may be technical in nature – such as a query component, or business focused – such as a “customer” component. These components will integrate under a common technology – such as J2EE.

Program Components provide the capability for drag-and-drop assembly of applications from fine-grain parts.

Note that some Program Components will provide access to the “outside world”, such as CORBA or XML thus making a set of Program Components into a larger grain component.

The destination between Program Components and all others is quite important as these are the only components that do not use some kind of distributed technology – they are only used and visible within the context of “a program.”

2.7.3.5 Relationships between ProcessComponent levels

Relationships between ProcessComponent levels

Figure 2-3 shows how configurations of ProcessComponents at one level may use and be composed of ProcessComponents at lower levels. It also shows that at any level ProcessComponents may be primitive, that is – directly implemented without being a Composition. ProcessComponents may re-use and compose ProcessComponents at lower levels or the same level.
There is no requirement or expectation that an EDOC computational specification must use all of these levels. For example, an E-Business Component could be directly composed of Program Components or it could use every levels.

2.8 Information Specification

2.8.1 Concepts

The information specification defines the semantics of information and information processing involved in the parts of the business processes carried out by the EDOC system (or by components that comprise that system). The information specification concepts are taken from the RM-ODP Part 3 Clause 6 (see Appendix A [3]).

The information specification is expressed in terms of

- a configuration of information objects (static schema),
- the behavior of those information objects (dynamic schema), and
- the constraints that apply to either of the above (invariant schema).

The information objects identified correspond to enterprise objects in the enterprise specification for which information is held and processed by the system.

The structure of the information objects and the relationships between them are defined in terms of static (structural) configurations of information objects. This includes the structure of individual information objects and the structure comprising a set of related information objects.

The behavior of the interrelated information objects is defined in terms of state changes that can occur and relate to the effects of the process steps in the enterprise specification.
The constraints relate to the business rules that apply to the process steps in the enterprise specification and define predicates on the information objects that must always be true.

### 2.8.2 EDOC Information Specifications

An EDOC information specification makes use of the Entities profile and the Relationships profile for the basic definition of the information structure, where:

- information objects are modeled as Entities and Relationships;
- constraints are defined in terms of enumerated states, relationship properties, and invariants from UML.

It makes use of the Choreography from the CCA for the definition of behavior of Entities in terms of changes of EntityState.

It makes use of the Relationships profile for rigorous specification of relationships.

### 2.9 Engineering Specification

#### 2.9.1 Concepts

The engineering specification defines the distribution transparency requirements and the services required to provide these transparencies in support of the processing specified by the computational specification. In addition, the engineering specification describes the means by which distribution is provided. The engineering specification concepts are taken from the RM-ODP Part 3 Clause 8 (see Appendix A [3]).

The engineering specification is derived from the computational specification by applying a technology mapping. The technology mapping incorporates standard interface and naming protocols to define consistent interface types and specifications.

The engineering specification will also incorporate additional design decisions. One of the key aspects of the engineering specification is the strategy for distributed computing, governing such issues as:

- which objects are network accessible and which are not; objects that are not network accessible must be co-located with objects with which they have relationships or from which they receive messages;
- the scope of transactions and the use of asynchronous messaging;
- which elements are persistent and how they are mapped to a persistent data store.

The engineering specification provides the basis for code generation. Currently, the ECA elements along with current UML design facilities can provide specifications for code to implement the objects, their interfaces, code to assure model integrity and methods to support certain services and protocols. Humans will still be required to program the business logic of methods and processes.
2.9.2 EDOC Engineering Specifications

These are defined by mapping from the computational specification to a technology abstraction model such as FCM. Examples of such mappings are given in Section II.

2.10 Technology Specification

The technology specification is concerned with the choice and deployment of software and hardware products for implementing the system and with the associated mappings from technology abstraction models such as FCM to the corresponding technologies (e.g. J2EE with EJB, Flow Composition Model (FCM), CORBA 3 with CCM and MS DNA/.Net with DCOM).

2.11 Specification Integrity - Interviewpoint Correspondences

This section identifies relationships that are required to exist between viewpoint specifications and are expressed through relationships between elements in different viewpoint specifications.

2.11.1 Computational-Enterprise Interrelationships

A Process in the computational specification is related one or more sets of Activities in one or more Processes in the enterprise specification, where performance of those Activities is the responsibility of the EDOC system. It may also be related to Business Rules that apply to those Activities.

An Entity in the computational specification is related to an Entity referenced (as an artifact) in at least one Activity in a Process in the enterprise specification, where the Activity is the responsibility of the EDOC system.

A BusinessNotification in the computational specification is related to a BusinessNotification associated with an Activity in a Process in the enterprise specification, where the Activity is the responsibility of the EDOC system.

A Rule in the computational specification is related to a Rule that applies to Activities in one or more Processes in the enterprise specification, where the Activities are the responsibility of the EDOC system.

2.11.2 Computational-Information Interrelationships

A Entity in the computational specification is related to an entity or a configuration of Entities in a static schema in the information specification.

A Process in the computational specification is related to a Choreography in the information description and can be related also to an invariant schema.

A BusinessNotification in the computational specification is related to a Choreography in the information description.
A Rule in the computational specification is related to an invariant schema in the information specification.

### 2.11.3 Computational-Engineering Interrelationships

These depend upon the specific technology mappings that are applied.

### 2.11.4 Engineering-Technology Interrelationships

These depend upon the specific technology mappings that are applied.

Section I - ECA Design Rationale

This chapter describes the Enterprise Collaboration Architecture (ECA) – a model-driven architecture approach for specifying Enterprise Distributed Object Computing systems.

3.1 Key Design Features

Five key design features of the ECA address the EDOC vision:

- Recursive component composition;
- Support for event-driven systems;
- Process specification;
- Integration of process and information models;
- Technology independence, allowing implementation of a design using different technologies.
3.1.1 Recursive component composition

Business processes are by their very nature collaborations – a set of people, departments, divisions or companies, working together to achieve some purpose or set of purposes.

Such a collaboration can be viewed as a “composition” with the people, departments etc. as “components” of that composition having “roles” that represent how each component is to behave within the composition (note that the same component may have different roles in the same or different compositions, just as a person, department etc. may have many roles with respect to many processes).

This dynamic of component and composition is fundamental, the concept of component only makes sense with respect to some specific kind of composition and the concept of composition only makes sense when there can be components to compose it.

When a high-level business process is considered, such as buying and selling, there are roles within this buy-sell process for the buyer and seller. In some cases there may be other roles, such as banks, freight forwarders and brokers. Each of these is defined as a component within the high-level process, e.g. it is a component of the “buy-sell” process, playing some role.

Besides identifying the roles it is necessary to identify how each of the components must interact with the other components for the process to unfold. Thus, for each kind of interaction that exists between roles there is a protocol for that interaction defined by the information that flows and the timing of that flow, for example the interaction of the seller with a freight forwarder is completely different from the interaction with the buyer. This leads to the next important concept – that of interactions. Interactions are well defined protocols between roles within some composition. Each interaction point on a component is called a “port”, which is the point of interaction of roles.

Finally, reflecting what is seen in the world, it is necessary to allow “drill down” from one level of granularity to another. When you place an order on the web you see a single face (the web portal) playing a single role (the seller). This simplified view represents the seller’s role in the buy-sell process (you represent the other role). Inside of the seller, when it is opened up, you see order processing, credit, warehousing, shipping – all of the roles it takes to get you your order. This more fine-grain process represents the way a particular component has been configured to play the role of the seller, another seller may involve other choices.

Adding this concept of drill-down takes us from “flat” component composition to recursive component composition – the ability to define components as compositions of finer grain components.

Thus, components are defined in terms of sub-components playing roles and interacting through ports. At the highest level, processes are self-contained, the entire community of roles is identified. When you “open up” one of the components you may find a “primitive” component, one defined in terms of pre-established constructs such as may be found in Java or the UML Action language. The other thing you may find is another composition. What looks like an atomic component at one level may reveal a complex lattice of sub-components when “opened up”.

A recursive component architecture can be used “top down”, by defining new processes in terms of higher level compositions. It can also be used “bottom up” by assembling existing components into new compositions – making new components. As new basic capabilities are required they can either be defined from existing components or new primitive components can be supplied, so there is no “brick wall” when some fundamental capability you need was not anticipated.

In such a recursive component architecture there is a clear separation between the “inside” of a component and its “outside”. The outside of a component exposes a set of named ports, each with a defined interaction that connects it with a compatible port in another component. These ports specify what information flows between the compatible components and under what conditions the information flows. The outside of a component is not concerned with the internal composition or process of the component.

One other aspect of component technology is that of configurability. Components may be very general in nature, which promotes reuse. These very general components must be configured when used in a specific role. This may be seen in the property panels of bean-boxes or COM components. The ability to configure a component is essential to making it general and reusable. We call a configuration point a “property”.

To summarize the points;

- The concepts of component and composition are fundamentally tied.
- Components may be primitive or compositions of sub-components
- Each component can play roles within other compositions.
- Components interact with each other, within composite processes, through ports.
- Component composition is recursive, allowing decomposition and assembly.

The advantages of this approach are

- A single simple paradigm describes large grain and fine grain process components.
- Components are reusable across many compositions
- New components may be defined as collaborations of existing components
- New fundamental capabilities may defined as primitive components.
- The collaborative and recursive nature of processes may be directly represented.

### 3.1.2 Process Specification

The Business Process profile specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model system behavior in the context of the business it supports.

The profile provides modeling concepts that allow the description of business processes in terms of a composition of business activities, selection criteria for the entities that carry out these activities, and their communication and coordination. In particular, the Business Process profile provides the ability to express:
complex dependencies between individual business tasks (i.e. logical units of work) constituting a business process, as well as rich concurrency semantics;

representation of several business tasks at one level of abstraction as a single business task at a higher level of abstraction and precisely defining relationships between such tasks, covering activation and termination semantics for these tasks;

representation of iteration in business tasks;

various time expressions, such as duration of a task and support for expression of deadlines;

support for the detection of unexpected occurrences while performing business tasks that need to be acted upon, i.e. exceptional situations;

associations between the specifications of business tasks and business roles that perform these tasks and also those roles that are needed for task execution;

initiation of specific tasks in response to the occurrence of business events;

the exposure of actions that take place during a business process as business events.

The modeling of processes in the ECA profile addresses an RFP requirement, but, more importantly, processes are important elements in the representation of interactions between components, systems and enterprises. Processes are the mechanisms of collaborations. Processes define the roles of the participants and artifacts involved in collaborations. Processes also define the manner in which events can drive the operation of the enterprise. Consequently, it is essential that the ECA model include a representation of processes that enables a modeler to define a framework for the operation of an enterprise.

The modeling of processes in the ECA profile reflects the OMG Workflow Management Facility model. A process contains activities, which perform the actions of the process. The activities may invoke other processes, and they may employ resources. The Workflow Management Facility resource interface represents the participation of that resource, i.e., a role in the ECA context. The resource/role captures the state and supports the interaction between the activity and a potentially wide variety of resources.

The ECA model goes slightly beyond the Workflow Management Facility specification. First, it extends the resource concept by defining performers and artifacts (active and passive participants). Second, it adds the ability to attach pre and post conditions to activities. These are concepts that are consistent with workflow management concepts and provide basic flow control mechanisms. These were not addressed in the Workflow Management Facility specification because it focused primarily on interoperability between workflow management systems.

The ECA profile does not attempt to define a representation of the action semantics of processes, nor does it define the relationship of processes to organizations or applications. These are left to other RFPs to be addressed by specialists in these areas.
3.1.3 Specification of Event Driven Systems

Event driven computing is becoming the preferred distributed computing paradigm in many enterprises and in many collaborations between enterprises. Event driven computing combines two kinds of loosely coupled architectures.

The first one is loosely coupled, distributed components that communicate with each other through asynchronous messaging.

The other one is loosely coupled business process execution. Here enterprises collaborate under an overall long term contract, but do not execute their day to day interaction in traditional workflow, or request/response style interaction.

In event driven computing the most important aspect of a process is the events that happen during its execution, and the most important part of the component-to-component communication is the notification of such events from the party that made them happen to all the parties that need to react to them.

In ECA we support both the definition of loosely coupled business processes, as well as the loosely coupled communication between distributed components.

Neither the world, nor the computing world, however, apply only one paradigm to their problem space. Businesses use a combination of loosely coupled and tightly coupled processes, and computing solutions deploy a combination of loosely coupled and tightly coupled styles of communication and interaction between distributed components.

An ECA process can be defined as event driven for some of its steps and workflow or request/response driven for others. ECA distributed components can be configured to communicate with each other in a mixture of event-driven publish-and-subscribe, asynchronous peer-to-peer, and client-server remote invocation styles.

The essential elements of the purely event driven approach are:

- Business Process objects are configured with a set of Business Rule parameters that determine what Business Events trigger actions, and what the action should be.
- Business Process objects operate on Business Entity objects which represent people, products, and other business resources and artifacts.
- When actions are performed on Business Entity objects, Business Events happen.
- All Business Entity objects are capable of notifying the world of events that happen to them.
- All Business Process objects are capable of subscribing to such events and interpreting them throughout their set of business rules.

3.1.4 Integration of Process and Information Models

IT systems are specified with entity and process models, where entity models describe the things (entities, attributes, relationships, invariants) in the IT system and process models specify the processes, sub-processes, activities, resources, roles, and rules of IT system behavior.
Information modeling tools, such as those based on the UML metamodel, are used to specify entity models. Process definition tools, such as those provided by BPR and workflow vendors, are used to specify process models. As these entity model and process model tools are based on different metamodels, the integration of their models into the IT system specification is a problem.

IT system designers and developers typically work round the problem by looking at one model, then the other, and then do their own composition for that moment (perhaps influenced by memories of other compositions). One result of this is that the normative entity and process models when composed, by each individual at multiple moments in time, become non-normative individual interpretations of the IT system specification. Also of concern is the impact of model changes to the composition – evolution of process and entity models is reasonably certain, especially during IT system development projects.

This specification specifies how the UML metamodel may be extended to become a common underlying metamodel for expressing IT system entities, processes, and their relationships. Although entity and process modeling styles are very different, their underlying metamodels are not and thus the process and information viewpoints can be reconciled.

With this metamodel UML, workflow, and BPR vendors can provide new tools that combine entity-orientated and process-orientated modeling techniques to produce integrated IT system models.

### 3.1.5 Rigorous relationship specification

Rigorous relationship specification is a major aspect of business modeling and software modeling. The semantics of a class diagram is shown in its structure – the collections of “lines” – that has to be defined by means of appropriate invariants and represented graphically. Moreover, relationships are fundamental to behavior because they are the paths over which actions occur, therefore clear, concise and rigorous specification of relationship semantics is of utmost importance.

Multiplicities are not the most important or most interesting properties of relationships¹. Property determinations are much more important for the semantics of a relationship, and distinguish among different kinds of relationships. The fragments of relationship invariants about property determination represent an essential fragment of those elusive “business rules” that are the backbone of a good specification and that should never be only “in the code.”

---

¹ In most cases, the multiplicities follow from the generic relationship invariant and therefore do not need to be explicitly shown in the diagram: the Stereotype takes care of that. Such diagrams are less cluttered.
At the same time, it is very desirable to discover and specify – rather than reinvent – those kinds of relationships that are encountered in all specifications, so that reuse at the specification level becomes possible. Such generic relationships extend the set of reusable constructs that already exist in UML.

It is also desirable that the approach taken for the specification of relationships should be extensible so that, if it appears that in a particular business (or a set of applications) additional generic relationships are needed and useful, then they may be precisely and explicitly defined and added in a manner similar to the existing definitions.

Generic relationships can provide concepts and constructs that permit UML to be used for specification of businesses and systems in a more rigorous manner than (and without restrictions currently imposed by) the base UML 1.3. Generic relationships can provide for explicit specification of relationship semantics in class diagrams, a line between boxes – even a named line! – should not be considered an adequate relationship specification.²

3.1.6 Mappings to Technology - Platform Independence

Viewpoint abstractions in the context of model-based development provide mechanisms for specifying platform independent models of business applications.

Such platform independence is an important element in systems that can adapt to change and, hence, is a fundamental element of the EDOC vision (). The rate of change of today’s enterprises and their requirements generates demands for flexible and dynamic systems that are capable of coping with the ever changing business requirements and with changes in software and hardware technologies.

---

² A combination of two interrelated lines required by the currently existing UML metamodel is an exception; specifically, an association line that simply mandates a link is acceptable, but only if it is paired with a <<Reference>> dependency line.
3.2 ECA Elements

The Enterprise Collaboration Architecture (ECA) comprises a set of five UML profiles. Each profile consists of a set of UML extensions that represent concepts needed to model specific aspects of EDOC systems and address specific aspects of the key design features. The concepts are described in terms of UML profiles. The semantics of each profile (except for the Relationships Profile) are also expressed in a UML-independent MOF metamodel. These profiles are defined in the remainder of this chapter:

- the Component Collaboration Architecture (CCA) which details how the UML concepts of classes, collaborations and activity graphs can be used to model, at varying and mixed levels of granularity, the structure and behavior of the components that comprise a system – Section II;

- the Entities profile, which describes a set of UML extensions that may be used to model entity objects that are representations of concepts in the application problem domain and define them as composable components – Section III;

- the Events profile, which describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model event driven systems – Section IV;

- the Business Process profile, which specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model system behavior in the context of the business it supports – Section V;

- the Relationships profile, which describes the extensions to the UML core facilities to meet the need for rigorous relationship specification in general and in business modeling and software modeling in particular – Section VI.
The ECA profiles are technology independent and are used together to define platform independent models of EDOC systems in conformance with the MDA. In particular, they enable the modeling of the concepts that until now have had to be specified programmatically in terms of the use of services such as events/ notification, support for relationships and persistence.

Section II - The Component Collaboration Architecture

The Component Collaboration Architecture (CCA) details how the UML concepts of classes, collaborations and activity graphs can be used to model, at varying and mixed levels of granularity, the structure and behavior of the components that comprise a system.

3.3 Rationale

3.3.1 Problems to be solved

The information system has become the backbone of the modern enterprise. Within the enterprise, business processes are instrumented with applications, workflow systems, web portals and productivity tools that are necessary for the business to function.

While the enterprise has become more dependent on the information system the rate of change in business has increased, making it imperative that the information system keeps pace with and facilitates the changing needs of the enterprise.

Enterprise information systems are, by their very nature, large and complex. Many of these systems have evolved over years in such a way that they are not well understood, do not integrate and are fragile. The result is that the business may become dependent on an information infrastructure that cannot evolve at the pace required to support business goals.

The way in which to design, build, integrate and maintain information systems that are flexible, reusable, resilient and scalable is now becoming well understood but not well supported. The CCA is one of a number of the elements required to address these needs by supporting a scalable and resilient architecture.

The following subsections detail some of the specific problems addressed by CCA.

3.3.1.1 Recursive decomposition and assembly

Information systems are, by their very nature, complex. The only viable way to manage and isolate this complexity is to decompose these systems into simpler parts that work together in well-defined ways and may evolve independently over time. These parts can than be separately managed and understood. We must also avoid re-inventing parts that have already been produced, by reusing knowledge and functionality whenever practical.
The requirements to decompose and reuse are two aspects of the same problem. A complex system may be decomposed “top down”, revealing the underlying parts. However, systems will also be assembled from existing or bought-in parts – building up from parts to larger systems.

Virtually every project involves both top-down decomposition in specification and “bottom up” assembly of existing parts. Bringing together top-down specification and bottom-up assembly is the challenge of information system engineering.

This pattern of combining decomposition in specification and assembly of parts in implementation is repeated at many levels. The composition of parts at one level is the part at the next level up. In today’s web-integrated world this pattern repeats up to the global information system that is the Internet and extends down into the technology components that make up a system infrastructure – such as operating systems, communications, DBMS systems and desktop tools.

Having a rigorous and consistent way to understand and deal with this hierarchy of parts and compositions, how they work and interact at each level and how one level relates to the next, is absolutely necessary for achieve the business goals of a flexible and scalable information systems.

### 3.3.1.2 Traceability

The development process not only extends “up and down” as described above, but also evolves over time and at different levels of abstraction. The artifacts of the development process at the beginning of a project may be general and “fuzzy” requirements that, as the project progresses, become precisely defined either in terms of formal requirements or the parts of the resulting system. Requirements at various stages of the project result in designs, implementations and running systems (at least when everything goes well!). Since parts evolve over time at multiple levels and at differing rates it can become almost impossible to keep track of what happened and why.

Old approaches to this problem required locking-down each level of the process in a “waterfall”. Such approaches would work in environments where everything is known, well understood and stable. Unfortunately such environments seldom, if ever, occur in reality. In most cases the system becomes understood as it evolves, the technology changes, and new business requirements are introduced for good and valid reasons. Change is reality.

Dealing with this dynamic environment while maintaining control requires that the parts of the system and the artifacts of the development process be traceable both in terms of cause-effect and of changes over time. Moreover, this traceability must take into account the fact that changes happen at different rates with different parts of the system, further complicating the relationships among them. The tools and techniques of the development process must maintain and support this traceability.
3.3.1.3 Automating the development process

In the early days of any complex and specialized new technology, there are “gurus” able to cope with it. However, as a technology progresses the ways to use it for common needs becomes better understood and better supported. Eventually those things that required the gurus can be done by “normal people” or at least as part of repeatable “factory” processes. As the technology progresses, the gurus are needed to solve new and harder problems – but not those already solved.

Software technology is undergoing this evolution. The initial advances in automated software production came from compilers and languages, leading to DBMS systems, spreadsheets, word processors, workflow systems and a host of other tools. The end-user today is able to accomplish some things that would have challenged the gurus of 30 years ago.

This evolution in automation has not gone far enough. It is still common to re-invent infrastructures, techniques and capabilities every time a new application is produced. This is not only expensive, it makes the resulting solutions very specialized, and hard to integrate and evolve.

Automation depends on the ability to abstract away from common features, services, patterns and technology bindings so that application developers can focus on application problems. In this way the ability to automate is coupled with the ability to define abstract viewpoints of a system – some of which may be constant across the entire system.

The challenge today is to take the advances in high-level modeling, design and specification and use them to produce factory-like automation of enterprise systems. We can use techniques that have been successful in the past, both in software and other disciplines to automate the steps of going from design to deployment of enterprise scale systems. Automating the development process at this level will embrace two central concepts; reusable parts, and model-based development. It will allow tools to apply pre-established implementation patterns to known modeling patterns. CCA defines one such modeling pattern.

3.3.1.4 Loose coupling

Systems that are constructed from parts and must survive over time, and survive reuse in multiple environments, present some special requirements. The way in which the parts interact must be precisely understood so that they can work together, yet they must also be loosely coupled so that each may evolve independently. These seemingly contradictory goals depend on being able to describe what is important about how parts interact while specifically not coupling that description to things that will change or how the parts carry out their responsibility.

Software parts interact within the context of some agreement or contract – there must be some common basis for communication. The richer the basis of communication the richer the potential for interaction and collaboration. The technology of interaction is generally taken care of by communications and middleware while the semantics of interaction are better described by UML and the CCA.
So while the contract for interaction is required, factors such as implementation, location and technology should be separately specified. This allows the contract of interaction to survive the inevitable changes in requirements, technologies and systems.

Loose coupling is necessarily achieved by the capability of the systems to provide “late binding” of interactions to implementation.

### 3.3.1.5 Technology Independence

A factor in loose coupling is technology independence i.e. the ability to separate the high-level design of a part or a composition of parts from the technology choices that realize it. Since technology is so transient and variations so prevalent it is common for the same “logical” part to use different technologies over time and interact with different technologies at the same time. Thus a key ingredient is the separation high-level design from the technology that implements it. This separation is also key to the goal of automated development.

### 3.3.1.6 Enabling a business component Marketplace

The demand to rapidly deploy and evolve large scale applications on the internet has made brute force methods of producing applications a threat to the enterprise. Only by being able to provision solutions quickly and integrate those solutions with existing legacy applications can the enterprise hope to achieve new business initiatives in the timeframe required to compete.

Component technologies have already been a success in desktop systems and user interfaces. But this does not solve the enterprise problem. Recently the methods and technologies for enterprise scale components have started to become available. These include the “alphabet soup” of middleware such as XML, CORBA, Soap, Java, ebXML, EJB & .net,. What has not emerged is the way to bring these technologies together into a coherent enterprise solution and component marketplace.

Our vision is one of a **simple** drag and drop environment for the **assembly** of **enterprise components** that is integrated with and leverages a **component marketplace**. This will make buying and using a software component as natural as buying a battery for a flashlight.

### 3.3.1.7 Simplicity

A solution that encompasses all the other requirements but is too complex will not be used. Thus our final requirement is one of simplicity. A CCA model must make sense without too much theory or special knowledge, and must be tractable for those who understand the domain, rather than the technology. It must support the construction of simple tools and techniques that assist the developer by providing a simple yet powerful paradigm. Simplicity needs to be defined in terms of the problem – how simply can the paradigm solve my business problems. Simplistic infrastructure and tools that make it hard to solve real problems are not viable.
3.3.2 Approach

Our approach to these requirements is to utilize the Unified Modeling Language (UML) as a basis for an architecture of recursive decomposition and assembly of parts. CCA profiles three UML diagrams and adds one optional diagram.

3.3.2.1 Class Structure (Structure)

The class structure is used to show the structure of ProcessComponents and the information which flows between them.

3.3.2.2 Statecharts (Choreography)

Statecharts are used to specify the dynamic (or temporal) contract of protocols and components, when messages should be sent or received on various ports. The Choreography specifies the intended external behavior of a component, either by specifying transitions directly on its ports or indirectly via its protocols.

3.3.2.3 Collaborations (Composition)

Collaborations are used to show the composition of a ProcessComponent (or community) by using a set of other ProcessComponents, configuring them and connecting them together.

3.3.2.4 CCA Notation (Structure & Composition)

CCA Also defines a notation which integrates the ProcessComponent structure and composition.

3.3.3 Concepts

At the outset it should be made clear that we are dealing with a logical concept of component - “part”, something that can be incorporated in a logical composition. It is referred to in the CCA as a ProcessComponent. In some cases ProcessComponents will correspond and have a mapping to physical components and/or deployment units in a particular technology.

Since CCA, by its very nature, may be applied at many levels, it is intended that CCA be further specialized, using the same mechanisms, for specific purposes such as Business-2-Business, e-commerce, enterprise application integration (EAI), distributed objects, real-time etc.

It is specifically intended that different kinds and granularities of ProcessComponents at different levels will be joined by the recursive nature of the CCA. Thus ProcessComponents describing a worldwide B2B business process can decompose into application level ProcessComponents integrated across the enterprise which can decompose into program level ProcessComponents within a single system. However,
this capability for recursive decomposition is not always required. Any ProcessComponent’s part may be implemented directly in the technology of choice without requiring decomposition into other ProcessComponents.

The CCA describes how ProcessComponents at a given level of specification collaborate and how they are decomposed at the next lower level of specification. Since the specification requirements at these various levels are not exactly the same, the CCA is further specialized with profiles for each level. For example, ProcessComponents exposed on the Internet will require features of security and distribution, while more local ProcessComponents will only require a way to communicate.

The recursive decomposition of ProcessComponents utilizes two constructs in parallel: composition (using UML Collaboration) to show what ProcessComponents must be assembled and how they are put together to achieve the goal, and choreography (the UML Statechart) to show the coordination of activities to achieve a goal. The CCA integrates these concepts of “what” and “when” at each level.

Concepts from the Object Oriented Role Analysis Method (OORAM) and Real-time Object Oriented Modeling (ROOM) have been adapted and incorporated into CCA.

### 3.3.3.1 What is a Component Anyway?

There are many kinds of components – software and otherwise. A component is simply something capable of composing into a composition – or part of an assembly. There are very different kinds of compositions and very different kinds of components. For every kind of component there must be a corresponding kind of composition for it to assemble into. Therefore any kind of component should be qualified as to the type of composition. CCA does not claim to be “the” component model, it is “a” component model with a corresponding composition model.

CCA ProcessComponents are processing components, ones that collaborate with other CCA ProcessComponents within a CCA composition. CCA ProcessComponents can be used to build other CCA ProcessComponents or to implement roles in a process – such as a vendor in a buy-sell process. The CCA concepts of component and composition are interdependent.

There are other forms of software and design components, including UML components, EJBs, COM components, CORBA components, etc. CCA ProcessComponents and composition are orthogonal to these concepts. A technology component, such as an EJB may be the implementation platform for a CCA ProcessComponent.

Some forms of components and compositions allow components to be built from other components, this is a recursive component architecture. CCA is such a recursive component architecture.
3.3.3.2 ProcessComponent Libraries

While the CCA describes the mechanisms of composition it does not provide a complete ProcessComponent library. ProcessComponent libraries may be defined and extended for various domains. A ProcessComponent library is essential for CCA to become useful without having to re-invent basic concepts.

3.3.3.3 Execution & Technology profiles

The CCA does not, in itself, specify sufficient detail to provide an executable system. However, it is a specific goal of CCA that when a CCA specification is combined with a specific infrastructure, executable primitive ProcessComponents and a technology profile, it will be executable.

A technology profile describes how the CCA or a specialization of CCA can be realized by a given technology set. For example, a technology profile for Java may enable Java components to be composed and execute using dynamic execution and/or code generation. A technology profile for CORBA may describe how CORBA components can be composed to create new CORBA components and systems. In RM-ODP terms, the technology profile represents the engineering and technology specifications.

Some technology profiles may require additional information in the specification to execute as desired; this is generally done using tagged values in the specification and options in the mapping. The way in which technology specific choices are combined with a CCA specification is outside of the scope of the CCA, but within the scope of the technology profile. For example, a Java mapping may provide a way to specify the signatures of methods required for Java to implement a component.

The combination of the CCA with a technology profile provides for the automated development of executable systems from high-level specifications.

For details of possible (non-normative) mappings from the CCA Profile to various engineering and technology options, see Section II of this specification.

3.3.3.4 Specification Vs. Methodology

The CCA provides a way to specify a system in terms of a hierarchical structure of Communities of ProcessComponents and Entities that, when combined with specifications prepared using technology profiles, is sufficiently complete to execute. Thus the CCA specification is the end-result of the analysis and design process. The CCA does not specify the method by which this specification is achieved. Different situations may require different methods. For example; a project involving the integration of existing legacy systems will require a different method than one involving the creation of a new real-time system – but both may share certain kinds of specification.
3.3.3.5 Notation

The CCA defines some new notations to simplify the presentation of designs for the user. These new notations are optional in that standard UML notation may be used when such is preferred or CCA specific tooling is not available. The CCA notation can be used to achieve greater simplicity and economy of expression.

3.3.4 Conceptual Framework

![Diagram showing the structure and dependencies of the CCA Metamodel](from CcaProfile)

Figure 3-2  Structure and dependencies of the CCA Metamodel

3.3.4.1 Process Component Specification

In keeping with the concept of encapsulation, the external “contract” of a CCA component is separate from how that component is realized. The contract specifies the “outside” of the component. Inside of a component is its realization – how it satisfies its contract. The outside of the component is the component specification. A component with only a specification is abstract, it is just the “outside” with no “inside.”

3.3.4.2 Protocols and Choreography

Part of a component’s specification is the set of protocols it implements. A protocol specifies what messages the component sends and receives when it collaborates with another component and the choreography of those messages – when they can be sent and received. Each protocol the component supports is provided via a “port”, the connection point between components.

Protocols, ports and choreography comprise the contract on the outside of the component. Protocols are also used for large-grain interactions, such as for B2B components.
The protocol specifies the conversation between two components (via their ports). Each component that is using that protocol must use it from the perspective of the “initiating role” or the “responding role”. Each of these components will use every port in the protocol, but in complementary directions.

For example, a protocol “X” has a flow port “A” that initiates a message and a flow port “B” that responds to a message. Component “Y” which responds to protocol “X” will also receive “A” and initiate “B”. But, Component “Z” which initiates protocol “X” will also initiate message “A” and respond to message “B” – thus initiating a protocol will “invert” the directions of all ports in the protocol.

3.3.4.3 Primitive and Composed Components

Components may be abstract (having only an outside) or concrete (having an inside and outside). Frequently a concrete component inherits its external contract from an abstract component – implementing that component.

There may be any number of implementations for a ProcessComponent and various ways to “bind” the correct implementation when a component is used.

The two basic kinds of concrete components are:

- **primitive components** – those that are built with programming languages or by wrapping legacy systems.

- Composed Components – Components that are built from other components; these use other components to implement the new components functionality. Composed components are defined using a composition.

3.3.4.4 Composition

Compositions define how components are used. Inside of a composition components are used, configured and connected. This connected set of component usages implements the behavior of the composition in terms of these other components – which may be primitive, composed or abstract components.

Compositions are used to build composed components out of other components and to describe community processes – how a set of large grain components works together for some purpose. Components used in a community process represent the roles of that process.

Central to compositions are the connections between components, values for configuration properties and the ability to bind concrete components to a component usage.

3.3.4.5 Document & Information Model

The information that flows between components is described in a Document Model, the structure of information exchanged. The document model also forms the basis for information entities and a generic information model. The information model is acted on by CCA ProcessComponents (see the Entities profile, Section III, below).
3.3.4.6 Model Management

To help organize the elements of a CCA model a “package” structure is used exactly as it is used in UML. Packages provide a hierarchical name space in which to define components and component artifacts. Model elements that are specific to a process, protocol or component may also be nested within these, since they also act as packages.
3.4 CCA Metamodel

Figure 3-3 is a combined model of the major elements of the CCA component specification defined below.
3.4.1 Structural Specification

The structural specification represents the physical structure of the component contract, defining the component and its ports.

A **ProcessComponent** represents the contract for a component that performs actions – it “does something”. A ProcessComponent may define a set of **Ports** for interaction with other ProcessComponents. The ProcessComponent defines the external contract of the component in terms of ports and a **Choreography** of port activities (sending or...
receiving messages or initiating sub-protocols). At a high level of abstraction a ProcessComponent can represent a business partner, other ProcessComponents represent business activities or finer-grain capabilities.

The contract of the ProcessComponent is realized via **ports**. A port defines a point of interaction between ProcessComponents. The simpler form of port is the **FlowPort**, which may produce or consume a single **data type**. More complex interactions between components use a **ProtocolPort**, which refers to a **Protocol**, a complete “conversation” between components. Protocols may also use other protocols as sub-protocols. Protocols, like ProcessComponents, are defined in terms of the set of ports they realize and the choreography of interactions across those ports. A protocol may optionally define names for the initiating and responding roles.

ProcessComponents may have **Property Definitions**. A property definition defines a configuration parameter of the component, which can be set, when the component is used.

The behavior of a ProcessComponent may be further specified by its **composition**, the composition shows how other components are used to define and implement the composite component. The specification of the ProcessComponent and protocol may include **Choreography** to sequence the actions of multiple ports and their associated actions. The actions of each port may be **Choreographed**. Composition and Choreography are defined in their own sections.

A ProcessComponent may have a **supertype** (derived from Choreography). One common use of supertype is to place abstract ProcessComponents within compositions and then produce separate realizations of those components as subtype composite or primitive components, which can then be substituted for the abstract components when the composition is used, or even at runtime.

An **Interface** represents a standard object interface. It may contain **OperationPorts**, representing call-return semantics, and FlowPorts – representing one-way operations.

A **MultiPort** is a grouping of ports whose actions are tied together. Information must be available on all sub-ports of the MultiPort for any action to occur within an attached component.

An **OperationPort** defines a port which realizes a typical request/response operation and allows ProcessComponents to represent both document oriented (FlowPort) and method oriented (OperationPort) subsystems.

### 3.4.1.1 ProcessComponent

**Semantics**

A ProcessComponent represents an active processing unit – it does something. A ProcessComponent may realize a set of Ports for interaction with other ProcessComponents and it may be configured with properties.

Each ProcessComponent defines a set of ports for interaction with other ProcessComponents and has a set of properties that are used to configure the ProcessComponent when it is used.
The order in which actions of the Process Component’s ports do something may be specified using Choreography. The choreography of a ProcessComponent specifies the external temporal contact of the ProcessComponent (when it will do what) based on the actions of its ports and the ports in protocols of its ports.

**UML base element(s) in the Profile and Stereotype**
Classifier Stereotyped as &lt;&lt;ProcessComponent&gt;&gt;

**Fully Scoped name**
ECA::CCA::ProcessComponent

**Owned by**
Package

**Extends**
Composition (indicating that the ProcessComponent may be composed of other ProcessComponents and that its ports may be choreographed).

Package (indicating that a ProcessComponent may own the specification of other elements).

UsageContext (indicating that the ProcessComponent may be the context for PortUsages representing the activities of its ports).

**Properties**

**Granularity**
A GranularityKind which defines the scope in which the component operates. The values may be:

- **Program** – the component is local to a program instance (default)
- **Owned** – the component is visible outside of the scope of a particular program but dedicated to a particular task or session which controls its life cycle.
- **Shared** – the component is generally visible to external entities via some kind of distributed infrastructure.

Specializations of CCA may define additional granularity values.

**UML Representation**

Tagged value

**isPersistent**
Indicates that the component stores session specific state across interactions. The mechanisms for management of sessions are defined outside of the scope of CCA.
**UML Representation**

Tagged value

**primitiveKind**

Components implementation includes additional implementation semantics defined elsewhere, perhaps in an action language or programming language. If the component has an implementation specification primitiveKind specifies the implementation specific type, normally the name of a programming language. If primitiveKind is blank, the composition is the full specification of the components implantation – the component is not primitive.

**UML Representation**

Tagged value

**primitiveSpec**

If primitiveKind has a value, primitiveSpec identifies the location of the implementation. The syntax of primitiveKind is implementation specific.

**Related elements**

**Ports** (via “PortOwner”)  
“Ports” is the set of Ports on the ProcessComponent. Each port provides a connection point for interaction with other components or services and realizes a specific protocol. The protocol may be simple and use a “FlowPort” or the protocol may be complex and use a “ProtocolPort” or an “OperationPort”. If allowed by its protocol, a port may send and receive information.

**UML Representation**

Required Aggregation Association from Port (Ports)

**Supertype (zero or one) , Subtypes (any number)**

A ProcessComponent may inherit specification elements (ports, properties & states (from Choreography) from a supertype. That supertype must also be a ProcessComponent. A subtype component is bound by the contract of its supertypes but it may add elements, override property values and restrict referenced types.

A component may be substituted by a subtype of that component.

**UML Representation**

Generalization
Properties (Any number)
To make a component capable of being reused in a variety of conditions it is necessary to be able to define and set properties of that component. Properties represents the list of properties defined for this component.

UML Representation
Classifier.feature referencing an attribute.

Constraints
A process component may only inherit from another process component.

3.4.1.2 Port

Semantics
A port realizes a simple or complex conversation for a ProcessComponent or protocol. All interactions with a ProcessComponent are done via one of its ports.

When a component is instantiated, each of its ports is instantiated as well, providing a well-defined connection point for other components.

Each port is connected with collaborative components that speak the same protocol. Multi-party conversions are defined by components using multiple ports, one for each kind of party.

Business Example: Flight reservation Port

UML base element(s) in the Profile and Stereotype
Class (abstract)

Fully Scoped name
ECA::CCA::Port

Owned by
ProcessComponent or Protocol via PortOwner

Extends
None
Properties

isTransactional
Indicates that interactions with the component are transactional & atomic (in most implementations this will require that a transaction be started on receipt of a message). Non-transactional components either maintain no state or must execute within a transactional component. The mechanisms for management of transactions are defined outside of the scope of CCA.

UML Representation
Tagged Value

isSynchronous
A port may interact synchronously or asynchronously. A port that is marked as synchronous is required to interact using synchronous messages and return values.

UML Representation
Tagged Value

name
The name of the port. The name will, by default, be the same as the name of the protocol role or document type it realizes.

UML Representation
ModelElement::name

Direction
Indicates that the port will either initiate or respond to the related type. An initiating port will send the first message. Note that by using ProtocolPorts a port may be the initiator of some protocols and the responder to others. The values of DirectionKind may be:

Initiates – this port will initiate the conversation by sending the first message.

Responds – this port will respond to the initial message and (potentially) continue the conversation.

UML Representation
Tagged Value and stereotype of “Owner” relation.

PostCondition
The status of the conversation indicated by the use of this port. This status may be queried in the postCondition of a transition.

UML Representation
Tagged Value
Related elements

“Owner” ProcessComponent or Protocol (Exactly One via PortOwner)
A Port specifies the realization of protocol by a ProcessComponent. This relation specifies the ProcessComponent that realizes the protocol.

UML Representation
Required aggregate association (Ports). This association will have a stereotype of “initiates” or “responds” to indicate “direction.”

Constraints
None

3.4.1.3 FlowPort

Semantics
A Flow Port is a port which defines a data flow in or out of the port on behalf of the owning component or protocol.

UML base element(s) in the Profile and Stereotype
Class stereotyped as <<FlowPort>>

Fully Scoped name
ECA::CCA::FlowPort

Owned by
PortOwner

Extends
Port

Properties
None

Related elements

type
The type of data element that may flow into or out of the port.

UML Representation
Required relation
3.4.1.4 ProtocolPort

Semantics
A protocol port is a port which defines the use of a protocol. A protocol port is used for potentially complex two-way interactions between components, such as is common in B2B protocols. Since a protocol has two “roles” (the initiator and responder), the direction is used to determine which role the protocol port is taking on.

UML base element(s) in the Profile and Stereotype
Class stereotyped as <<ProtocolPort>>

Fully Scoped name
ECA::CCA::ProtocolPort

Owned by
PortOwner

Extends
Port

Properties
None

Related elements
uses
The protocol to use, which becomes the specification of this port’s behavior.
3.4.1.5 OperationPort

**Semantics**
An operation port represents the typical call/return pattern of an operation. The OperationPort is a PortOwner which is constrained to contain only flow ports, exactly one of which must have its direction set to “initiates”. The other “responds” ports will be the return values of the operation.

**UML base element(s) in the Profile and Stereotype**
Operation (no stereotype)

Note1: The type of the “initiates” flow port will be the signature of the operation. Each attribute of the type will be one parameter of the operation.

Note2: Owned flow ports of postCondition==Success and direction=="responds” will be a return value for the operation. All other flow ports where direction=="responds” will correspond to an exception.

**Fully Scoped name**
ECA::CCA::OperationPort

**Owned by**
PortOwner (Protocol or ProcessComponent)

**Extends**
Port and PortOwner

**Properties**
None

**Related elements**

**Ports (Via PortOwner)**
The flow ports representing the call and returns.

**UML Representation**
Initiates ports – signature of the operation
Responds ports – return values of the operation.

**Constraints**
As a PortOwner, the OperationPort:
- May only contain FlowPorts.
- Must contain exactly one flow port with direction set to "responds."
- Must contain exactly one flow port with direction set to “initiates” (the call).

### 3.4.1.6 MultiPort

**Semantics**
A MultiPort combines a set of ports which are behaviorally related. Each port owned by the MultiPort will “buffer” information sent to that port until all the ports within the MultiPort have received data, at this time all the ports will send their data.

**UML base element(s) in the Profile and Stereotype**
Class stereotyped as <<MultiPort>>

**Fully Scoped name**
ECA::CCA::MultiPort

**Owned by**
PortOwner

**Extends**
Port & PortOwner

**Properties**
None

**Related elements**
- **Ports (Via PortOwner)**
The flow ports owned by the MultiPort.

**UML Representation**
Required aggregation association

**Constraints**
Owned ports will not forward data until all sub-ports have received data.
3.4.1.7 Protocol

Semantics

A protocol defines a type of conversation between two parties, the initiator and responder. One protocol role is the initiator of the conversation and the other the responder. However, after the conversation has been initiated, individual messages and sub-protocols may be initiated by either party. The ports of a protocol are specified with respect to the responder.

Within the protocol are sub-ports. Each port contained by a protocol defines a sub-action of that protocol until, ultimately, everything is defined in terms of FlowPorts.

A Protocol is also a choreography, indicating that activities of its ports (and, potentially their sub-ports) may be sequenced using an activity graph.

A protocol must be used by a two ProtocolPorts to become active.

The protocol specifies the conversation between two ProcessComponents (via their ports). Each component that is using that protocol must use it from the perspective of the “initiating role” or the “responding role.” Each of these components will use every port in the protocol, but in complementary directions.

For example, a protocol “X” has a flow port “A” that initiates a message and a flow port “B” that responds to a message. Component “Y” which responds to protocol “X” will also receive “A” and initiate “B”. But, Component “Z” which initiates protocol “X” will initiate message “A” and respond to message “B” – thus initiating a protocol will “invert” the directions of all ports in the protocol.

UML base element(s) in the Profile and Stereotype

Class stereotyped as <<Protocol>>

Fully Scoped name

ECA::CCA::Protocol

Owned by

Package

Extends

Choreography – Indicating that the contract of the protocol includes a sequencing of the port activities.

Package – Indicating that the protocol may contain the specification of other model elements (Most probably other protocols or documents).

Properties

None
Related elements

Ports (Via PortOwner)
The ports which define the sub-actions of the protocol. For example, a “callReturn” protocol may have a “call” FlowPort and a “return” FlowPort.

UML Representation
Required aggregate association

Initiator
The role which sends the first message in the protocol. Note that this is optional, in which case the initiating role name will be “Initiator”.

UML Representation
Required relation

Responder
The role which receives the first message in the protocol. Note that this is optional, in which case the responding role name will be “Responder”.

UML Representation
Required relation

Constraints
None

3.4.1.8 Interface

Semantics
An interface is a protocol constrained to match the capabilities of the typical object interface. It is constrained to only contain OperationPorts and FlowPorts and all of its ports must respond to the interaction (making interfaces one-way).

Each OperationPort or FlowPort in the Interface will map to a method. A ProtocolPort which initiates the Interface will call the interface. A ProtocolPort which Responds will implement the interface.

3.4.2 Choreography

A Choreography uses transitions to order usages of ports.

A Choreography specifies how messages will flow between PortUsages. The choreography may be externally oriented, specifying the contract a component will have with other components or, it may be internally oriented, specifying the flow of messages within a composition. External choreographies are shown as an activity graph while internal choreography is shown as part of a collaboration. An external choreography may be defined for a protocol or a ProcessComponent.
A **Choreography** uses **Connections** and **transitions** to order port messages as a state machine. Each “node” in the choreography must refer to a state or a port usage.

Choreography is an abstract capability that is inherited by ProcessComponents and protocols.

Initial, interim and terminating states are known as a “**PseudoState**” as defined in UML. CCA adds the pseudo states for success and failure end-states.

Ordering is controlled by **connections** between nodes (state and port usage being a kind of node). Transitions specify flow of control that will occur if the conditions (Precondition) are met. Transitions between port activities specify what should happen (contractually), while Connections between PortConnections specify what will happen at runtime.

### 3.4.2.1 Choreography

**Semantics**

An abstract class inherited by protocol and ProcessComponent which owns nodes and AbstractTransitions. A choreography specifies the ordering of port activities.

**UML base element(s) in the Profile and Stereotype**

Choreography - State Machine stereotyped as <<choreography>>: (context references classifier)

**Nodes**

The states and port usages to be choreographed.

**UML Representation**

PseudoState - StateMachine.top
PortActivity ::SubmachineState

AbstractTransitions
The connections and transitions between nodes.

UML Representation
Transition: StateMachine:transition
Connection: Collaboration::AssociationRole

Supertype (zero or one), Subtypes (any number)
A ProcessComponent, protocol or CommunityProcess may inherit specification elements (ports, properties & states (from Choreography) from a supertype. That supertype must also be a ProcessComponent. A subtype component is bound by the contract of its supertypes but it may add elements, override property values and restrict referenced types.

A component may be substituted by a subtype.

Constraints: The subtype-supertype relation may only exist between elements of the same meta-type. A ProcessComponent may only inherit from another ProcessComponent. A Protocol may only inherit from another Protocol and a CommunityProcess may only inherit from another CommunityProcess.

UML Representation
Generalization of classifier related by context.

3.4.2.2 Node

Semantics
Node is an abstract element that specifies something that can be the source and/or target of a connection or transition and thus ordered within the choreographed process. The nodes that do “real work” are PortUsages.

UML base element(s) in the Profile and Stereotype

None (Abstract)

**Fully Scoped name**
ECA::CCA::PortUsage

**Owned by**
Choreography

**Extends**
Node & Usage Context

**Properties**
None

**Related elements**

*extent*
The component, component usage or PortUsage to which the PortUsage is attached.

If the extent is a ComponentUsage the PortUsage must be a PortConnector for a port of the underlying ProcessComponent. This allows Connections between components being used within a composition.

If the extent is a PortUsage the PortUsage must represent a ProtocolPort which owns the represented usage. This allows the choreography of nested ports.
If the extent is a ProcessComponent the usage represents a port on the ProcessComponent and that ProcessComponent must be the composition owning both the port and the port usage. This allows Connections and transitions to be connected to the external ports of a component.

*UML Representation*
State machine: Owner of state machine
Collaboration: Association Role

*Represents*
The port which the PortUsage uses.

*UML Representation*
State machine: tagged value
Collaboration: ClassifierRole::base

*Constraints*
None

### 3.4.2.6 UsageContext

*Semantics*
When a port is used within a choreography it must be used within some context. UsageContext represents an abstract supertype of all elements that may be the context of a port. These are;

- ProcessComponent – as the owner of port activities and port connectors.
- ComponentUsage – as the owner of port connectors, representing the use of each of the component’s ports.
- PortUsages – representing ports nested via protocols.

*UML base element(s) in the Profile and Stereotype*
None (abstract)

*Fully Scoped name*
ECA::CCA::UsageContext

*Owned by*
None
3.4.2.7 PortActivity

Semantics
Port activity is state, part of the “contract” of a ProcessComponent or protocol, specifying the activation of a port such the ordering of port activities can be choreographed with transitions. A PortActivity (used with transitions) defines the contract of the component while a PortConnector (used with Connections) specifies the realization of a component’s actions in terms of other components.

UML base element(s) in the Profile and Stereotype
CompositeState Stereotyped as <<PortActivity>>

ECA::CCA::PseudoState

Owned by
Choreography

Extends
Node

Properties

Kind : PseudostateKind
- **choice** Splits an incoming transition into several disjoint outgoing transition. Each outgoing transition has a guard condition that is evaluated after prior actions on the incoming path have been completed. At least one outgoing transition must be enabled or the model is ill-formed.
- **fork** - Splits an incoming transition into several concurrent outgoing transitions. All the transitions fire together.
initial - The default target of a transition to the enclosing composite state.

join - Merges transitions from concurrent regions into a single outgoing transition. Join PseudoState will proceed after all its incoming Transition have triggered.

success - The end-state indicating that the choreography ended in success.

failure - The end-state indicating that the choreography ended in failure.

Related elements
None

Constraints
PseudoStates may only be connected using transitions.

3.4.3 Composition
Composition is an abstract capability that is used for ProcessComponents and for community processes. Compositions show how a set of components can be used to define and perhaps to implement a process.
A composition contains ComponentUsages to show how other ProcessComponents may be used to define the composite. Note that the same ProcessComponent may be used multiple times for different purposes. Each time a ProcessComponent is used,
each of its ports will also be used with a “**PortConnector**”. A port connector shows the connection point for each use of that component within the composition, including the ports on the component being defined.

Attached to a ProcessComponent usage are **PropertyValues**, configuring the ProcessComponent with properties that have been defined in property definitions.

A composition also contains a set of “**Connections**”. A connection joins compatible ports on ProcessComponents together to define a flow of data. The other side will receive anything sent out of one side. So a Connection is a form of logical event registration (one-way registration for a flow port or Operation port, two-way registration for a ProtocolPort).

A **Contextual Binding** allows realized ProcessComponents to be substituted for abstract ProcessComponents when a composition is used.

Compositions may be ProcessComponents or CommunityProcesses. **CommunityProcess** define a top-level process in terms of the roles played by process components representing actors in the process.

### 3.4.3.1 Composition

**Semantics**

Composition is an abstract class for CommunityProcesses or ProcessComponents. Compositions describe how instances of ProcessComponents (called ComponentUsages) are configured (with PropertyValues and ContextualBindings) and connected (with Connections) to implement the composed ProcessComponent or CommunityProcess.

**UML base element(s) in the Profile and Stereotype**

**UML Representation**
Collaboration:: ownedElement (Owned AssociationRoles)

**PortConnector (via Choreography and nodes)**
The port instances to be connected by Connections.

**UML Representation**
Collaboration:: (Owned ClassifierRoles)

**Constraints**
None

### 3.4.3.2 ComponentUsage

**Semantics**
A composition *uses* other ProcessComponents to define the process of the composition (a community process or ProcessComponent). “ComponentUsage” represents such a use of a component. The “uses” relation references the kind of component being used. Component Usage is part of the “inside” of a composed component.

The composition can be thought of as a template of ProcessComponent instances. Each component instance will have a “ComponentUsage” to say what kind of ProcessComponent it is, what its property values are and how it is connected to other ProcessComponents. A ComponentUsage will cause a ProcessComponent instance to be created at runtime (this instantiation may be real or virtual).
Each use of a ProcessComponent will carry with it a set of “portConnectors” which will be the connection points to other ProcessComponents.

**UML base element(s) in the Profile and Stereotype**

*UML Representation*
ClassifierRole::base

*PortsUsed (Via UsageContext)*
PortConnectors for each port on the used component.

*UML Representation*
AssociationRole
3.4.3.3 PortConnector

Semantics

The PortConnector provides a “connection point” for ComponentUsages within a composition and exposes the defined ports within the composition. The connections between PortConnectors are made with Connections.

PortConnections are “implied” by other model elements and will normally be created by design tools. PortConnections should be created as follows:

For each ComponentUsage there will be exactly one PortUsage for each port defined for the ProcessComponent being used.

For each port on the ProcessComponent being defined there will be exactly one PortUsage to support Connections to and from “outside” ports.

For each port within a protocol, OperationPort or MultiPort created for one of the above two reasons, a PortConnector may be created for each contained port. This allows Connections to be connected to finer grain elements, such as Connections within a protocol.

In summary, the “ProcessComponent” / “Port” pattern which defines the components external interface is essentially replicated in the “ComponentUsage” / “portConnector” part of the composition. Each time a component is used, each of its ports is used as well. Sub-ports of protocols also become PortConnectors.

UML base element(s) in the Profile and Stereotype

None
Related elements

Represents (via PortUsage)
The port of which this is a port.

Contexts (via PortUsage)
The associated owner of the port.

Incoming and Outgoing Connections (Via PortUsage and Node)
The Connections.

Constraints
PortConnectors are intended to be connected with Connections, Transitions may not be connected to a PortConnector

3.4.3.4 Connection

Semantics
A Connection connects two PortConnectors within a composition. Each port can produce and/or consume message events. The connection logically registers each port connector as a listener to the other, effectively making them collaborators.

A component only declares that given ports will produce or consume given messages, it doesn’t not know “who” will be on the other side. The composition shows how a ProcessComponent will be used within a context and thus how it will be connected to other components within that context. A Connection connects exactly two PortConnectors.

Connections may be distinguished from transitions in that Connections specify what events will flow between ProcessComponents while transitions specify the contract of port ordering.

UML base element(s) in the Profile and Stereotype
AssociationRole optionally stereotyped as <<Connection>>

Note: A Connection to a port contained by an interface will be represented by an operation, not a classifier. In this case the association role is directed to the ProtocolPort realizing the interface and a message attached with a call action referencing the operation in question.

Fully Scoped name
ECA::CCA::Connection

Owned by
Composition
**Extends**

**Related elements**

*Source and Target PortConnectors (Via PortUsage, Node & AbstractTransition)*
The PortConnectors between which the Connection is being defined.

**Constraints**
- The source and target nodes of a Connection must be PortConnectors.
- The source and target nodes must be port connectors owned by the same composition as the Connection.

### 3.4.3.5 PropertyValue

**Semantics**
To be useful in a variety of conditions, a ProcessComponent may have configuration properties—which are defined by a PropertyDefinition. When the component is used in a ComponentUsage those properties values may be set using a PropertyValue. These values will be used to construct or configure a component instance.

A PropertyValue should be included whenever the default property value is not correct in the given context.

Fills
The property being modified.

UML Representation
Constraint:constrainedElement referencing an attribute of <Owner>.

Constraints

“fills” must relate to a property definition of the ProcessComponent that the owner uses.

The type returned by the PropertyValue expression must be compatible with the type defined by the PropertyDefinition.

3.4.3.6 ContextualBinding

Semantics

A composition is able to use abstract ProcessComponents in compositions – we call these abstract compositions. The use of an abstract composition implies that at some point a concrete component will be bound to that composition. That binding may be done at runtime or when the composition is used as a component in another composition.

For example, a composed “Pricing” component may use an abstract component “PriceFormula.” In our “InternationalSales” composition we may want to say that “PriceFormula” uses “InternationalPricing.”

Contextual Binding allows the substitution of a more concrete ProcessComponent for a compatible abstract ProcessComponent when an abstract composed ProcessComponent is used. So within the composition that uses the abstract component (International
Sales) we say the use of a particular Component (use of PriceFormula) will be bound to a concrete component (InternationalPricing). These semantics correspond with the three relations out of ContextualBinding.

Note that other forms of binding may be used, including runtime binding. But these are out of scope for CCA. Some specializations of CCA may subtype ContextualBinding and apply selection formula to the binding, as is common in workflow systems.

An abstract composition may also be thought of as a pattern, with contextual binding being the parameter substitution.

**UML base element(s) in the Profile and Stereotype**

owner

The composition which is using the abstract composed component and wants to bind a more specific ProcessComponent for an abstract one. The owner of the ContextualBinding.

**UML Representation**

ModelElement::namespace

fills

The ComponentUsage which should have the ProcessComponent it uses replaced. This component usage does not have to be within the same composition as the contextual binding, it may be anywhere the component usage occurs visible from the scope of the composition owning the binding.
3.4.3.7 CommunityProcess

Semantics

Community processes may be thought of as the “top level composition” in a CCA specification, it is a specification of a composition of ProcessComponents that work together for some purpose other than specifying another ProcessComponent.

One kind of CommunityProcess would be a business process, in which case the nested components represent business partner roles in that process. For example, a community process could define the usage of a buyer, a seller, a freight forwarder and two banks for a sale and delivery process.

Note that designs can be done “top down” or as an assembly of existing ProcessComponents (bottom up). When design is being done top down, it is usually the CommunityProcess which comes first and then ProcessComponents specified to fill the roles of that process.

CommunityProcesses are also useful for standards bodies to specify the roles and interactions of a B2B process.

3.4.4 Document Model

The document model defines the information that can be transferred between and manipulated by ProcessComponents. It also forms the base for information in entities.

A data element represents a type of data which may either be primitive DataTypes or composite. CompositeData has named attributes which reference other types. Any type may have a DataInvariant expression.
Attributes may be `isByValue`, which are strongly contained or may simply reference other data elements provided by some external service. Attributes may also be marked as `required` and/or `many` to indicate cardinality. **DataTypes** define local data – these types are defined outside of CCA. **ExternalDocument** defines a document defined in an external type system. An **enumeration** defines a type with a fixed set of values.

### 3.4.4.1 DataElement

**Semantics**

DataElement is the abstract supertype of all data types. It defines some kind of information.

**UML base element(s) in the Profile and Stereotype**

Constraints applied to the values of this data type.

**Constraints**

None

### 3.4.4.2 DataType

**Semantics**

A primitive data type, such as an integer, string, picture, movie…
Primitive data types may have their structure and semantics defined outside of CCA. The following data types are defined for all specializations of CCA: String, Integer, Float, Decimal, Boolean.

**UML base element(s) in the Profile and Stereotype**

Extend

DataElements

Properties
None

Related elements

Feature
The attributes which form the composite.
UML Representation
Classifier.feature

Supertype
A type from which this type is specialized. The composite will include all attributes of all supertypes as attributes of itself.

Subtypes
The types derived from this type.

Constraints

3.4.4.6 Attribute

Semantics
Defines one “slot” of a composite type that may be filled by a data element of “type.”

UML base element(s) in the Profile and Stereotype
Attribute (No stereotype)

Fully Scoped name
ECA::DOCUMENTMODEL::Attribute

Owned by
CompositeData

Extends
None

Properties

isByValue
Indicates that the composite data is stored within the composite as opposed to referenced by the composite.

UML Representation
Stand-alone Tagged Value to apply to UML Attribute (a Stereotype of Attribute is not created to hold this TaggedValue :}
**required**
Indicates that the attribute slot must have a value for the composite to be valid.

*UML Representation*
StructuralFeature::multiplicity

**many**
Indicates that there may be multiple occurrences of values. These values are always ordered.

*UML Representation*
StructuralFeature::multiplicity

**initialValue**
An expression returning the initial value of the attribute.

*UML Representation*
Attribute::initialValue

**Related elements**

**type**
The type of information which the attribute may hold. Type instances may also be filled by a subtype.

*UML Representation*
StructuralFeature::type

**owner**
The composite of which this is an attribute.

*UML Representation*
ModelElement::namespace

**Constraints**
None

### 3.4.4.7 DataInvariant

**Semantics**
A constraint on the legal values of a data element.
UML base element(s) in the Profile and Stereotype
Constraint

Fully Scoped name
ECA::DOCUMENTMODEL::DataInvariant

Owned by
DataElement

Extends
None

Properties
Expression
The expression which must return true for the data element to be valid.

UML Representation
Constraint::body

isOnCommit (Default: False)
True indicates that the constraint only applies to a fully formed data element, not to one under construction.

UML Representation
Tagged Value

Related elements
ConstrainedElement
The data element that will be constrained.

UML Representation
Constraint::constrainedElement

3.4.4.8 ExternalDocument

Semantics
A large, self contained document defined in an external type systems such as XML, Cobol or Java that may or may not map to the ECA document model.
### UML base element(s) in the Profile and Stereotype

DataType Stereotyped as `<<ExternalDocument>>`

### FullyScoped name

ECA::DOCUMENTMODEL::ExternalDocument

### Owned by

Package

### Extends

DataElement

### Properties

All properties are tagged values

**MimeType**

The type of the document specified as a string compatible with the “mime” declarations.

**SpecURL**

A reference to an external document definition compatible with the mimeType, such as a DTD or Schema. If the MimeType does not define a specification form (E.G. GIF) then this attribute will be blank.

**ExternalName**

The name of the document within the SpecURL. For example, an element name within a DTD. If the MimeType does not define a specification form (E.G. GIF) or the specification form only specifies one document then this attribute will be blank.

### Related elements

None

### Constraints

None

### 3.4.5 Model Management

Model management defines how CCA models are structured and organized. It directly maps to its UML counterparts and is only included as an ownership anchor for the other elements.
A **package** defines a logical hierarchy of reusable model elements. Elements that may be defined in a package are **PackageContent** and may be ProcessComponents, Protocols, DataElements, CommunityProcesses and other packages. A **ImportedElement** defines a “shortcut” visibility of a package content in a package that is not its owner. Shortcuts are useful to organize reusable elements from different perspectives.

Note that ProcessComponents are also packages, allowing elements which are specific to that component to be defined within the scope of that component.

### 3.4.5.1 Package

**Semantics**

Defines a structural container for “top level” model elements that may be referenced by name for other model elements.
**UML base element(s) in the Profile and Stereotype**
Package

**Fully Scoped name**

ModelElement
The element to be imported.

Constraints
None

3.5 CCA Notation

CCA uses UML notation with a few extensions and conventions to make diagrams more readable and compact for CCA aware tools. The UML mapping shown how CCA is expressed in the UML Metamodel which has standard notation. Unless stated otherwise, all other UML elements use the base UML 1.4 notation. The following are additions this base UML 1.4 notation.

3.5.1 CCA Specification Notation

A ProcessComponent is based on the notation for a subsystem with extensions for ports and properties. Consider the following diagram template for ProcessComponent notation.

Figure 3-9 ProcessComponent specification notation
A ProcessComponent represents its external contract as a subsystem with the following addition:

- The ProcessComponent type may be represented as an icon in the component name compartment. “t” above.

- Ports are represented as going through the boundary of the box. The port itself is a smaller rectangle with the name of the port inside the rectangle. In the above, “Receives,” “Sends,” “Responder,” and “Initiator” are all ports. The type of the port is not represented in the diagram.

- Flow ports are represented as an arrow going through a box. Flow ports that send have the arrow pointing out of the box while flow ports that receive (Receives) have an arrow pointing into the box. A sender has the background and text color inverted.

- Protocol ports and Operation ports are boxes extending out of the component. Protocol ports representing an initiator have the colors of their background and text reversed. In the above, “Initiator” is a protocol port of an initiator and “Responder” is a protocol port that is not an initiator. ProtocolPorts may show nested, the Ports of the used Protocol.

- Multiports are shown as a shaded box grouping the set of ports it contains.

- Property Definitions are in a separate compartment listing the property name, type and default value (if any). The name, type and value are separated by lines. Each property is on a separate line.
3.5.2 Composite Component Notation

A composite is shown as a ProcessComponent with the composition in the center. The composition is a new notation but may also be rendered with a UML collaboration.

![Composite Component notation](image)

*Figure 3-11* - Composite Component notation (without internal ComponentUsages)
The ports on the composite component being defined are shown in the same way as they are on a ProcessComponent, but in this case represent the port connector.

A component usage is shown as a smaller version of a ProcessComponent inside the composite component. Note Usage (1..2) are component usages.

Port connectors are shown in the same fashion as ports, on component usages. The ports on Usage 1..2 are all port usages.

Connectors are shown as lines between port usages or port proxies. All the lines in the above are connectors.

Property values may be shown on component usages (in the same way as the property definition), or may be suppressed.
3.5.3 Community Process Notation

A community process is shown in the same way as a composite component with the exception that a community process has no external ports.

Figure 3-13 Community Process notation

In the above example “BuySellProcess” is a community process with component usage for “Buyer” and “Seller” which are connected via their “buy” and “sell” ports, respectively.

3.6 UML Profile

The CCA profile specifies how CCA concepts relate to and are represented in standard UML using stereotypes, tagged values and constraints. This allows off-the-shelf UML tools to represent CCA and interchange CCA models.

The CCA profile is organized as a single package which corresponds to the ECA::CCA package in the logical model and the CCA <<profile>> package. In addition there is a package for the document model which is used by CCA.

3.6.1 Tables mapping concepts to profile elements

The following tables provide a summary of the CCA elements as stereotypes and tagged values. These stereotypes and tagged values may be used in standard UML models, and represented in standard UML diagrams (See “Diagramming CCA” for an example).
### Table 3-1  Stereotypes for Structural Specification (UML notation: Class Diagram)

3.6.2 Introduction

The UML Profile for CCA accesses a number of UML Packages. The CCA `<profile>` extends these packages with CCA stereotypes & semantics.

![Diagram of UML «metamodel» and CCA «profile» Packages](image)

Each CCA stereotype extends a specific UML model element as shown below.
Figure 3-15  Stereotypes in the UML Profile for CCA

Constraints expressed generically

The set of all the «Port» of a «ProcessComponent» is the set of «Port» or its specializations, that are aggregated in the «ProcessComponent».

3. The “Relationships” header references the relationships in which the Model Element participates, and the name of the role in the relationship. The section "Relationships", see below, includes the specifications for these relationships, and their mapping between metamodel and UML representation.
The supertype of a «ProcessComponent» must be a «ProcessComponent».

**Formal Constraints Expressed in Terms of the UML Metamodel**

context ProcessComponent

inv:
    supertype->isEmpty() or
    supertype.isStereoKinded("ProcessComponent")

def:
    -- the Ports in the ProcessComponent :
    -- composed in the ProcessComponent

let ports : Set( Class) =
    (association->select( anAssociationEnd : AssociationEnd |
        anAssociationEnd.aggregationKind = ak_composite)
    ->association->connection - association)
    ->participant
    ->select( aClassifier : Classifier |
        anElement.isStereoKinded( «Port»))

**Diagram Notation**

N/A

### 3.6.3.3 «Port»

**Inheritance**

Foundation::Core::Class

«Port»

**Instantiation in a model**

Abstract

**Semantics**

Corresponds to the element of same name in the metamodel.

The «Port» stereotype has been introduced for clarity and brevity, defining in a common ancestor, the taggedValues corresponding to attributes of Port in the metamodel, and reused along the stereotypes specialization of «Port» : «FlowPort», «ProtocolPort», «MultiPort» and «OperationPort».
**Relationships**

<table>
<thead>
<tr>
<th>Relationship</th>
<th>Role(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ports</td>
<td>ports</td>
</tr>
<tr>
<td>Represents</td>
<td>represents</td>
</tr>
</tbody>
</table>

**Correspondence of metamodel attributes with UML attributes**

<table>
<thead>
<tr>
<th>Metamodel attribute name</th>
<th>UML attribute name</th>
<th>UML attribute owner</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td>ModelElement</td>
<td></td>
</tr>
</tbody>
</table>

**Tagged Values**

<table>
<thead>
<tr>
<th>Tagged Value name</th>
<th>Type</th>
<th>Multiplicity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isSynchronous</td>
<td>Boolean</td>
<td>1</td>
<td>default=false</td>

<tr>
<td>direction</td>
<td>DirectionKind</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>postCondition</td>
<td>«enumeration» Status</td>
<td>0..1</td>
<td></td>
</tr>
</tbody>
</table>

**Constraints expressed generically**

A «Port» must be aggregated into a «Protocol» or a «ProcessComponent», or a «MultiPort».

Note that the metamodel Interface corresponds in the UML Profile to a UML Classifier which may or may not be a UML Interface, and that the metamodel OperationPort corresponds to a UML Operation. However, UML Interface is the recommended model element to use. Although in the metamodel both Interface and OperationPort may contain other Port, in the UML Profile these, and their relationships are directly supported by UML. Neither Interface or OperationPort appear in the constraint below, as candidate owners for «Port». This allows arbitrary UML classifiers (of any kind) to be used with CCA. Only the operations of these classifiers will correspond to CCA elements.

The relationship between the Port and the PortOwner shall have the stereotype «<initiates>> or the stereotype «<responds>> which shall have the same value as “direction.”

**Formal Constraints Expressed in Terms of the UML Metamodel**

```plaintext
context Port
inv: aggregatedOwner->notEmpty()

3.6.3.7 UML Operation represents OperationPort

Semantics

The concept of OperationPort in the metamodel, is represented by a standard UML operation.

The OperationPort is constrained to contain only FlowPorts.
The signature, of the UML Operation representing an OperationPort, is derived from the type of the one and only FlowPort of the OperationPort, with direction="initiates". For each Attribute of the FlowPort, the UML Operation will have an input Parameter with type equal to the type of the Attribute in the FlowPort.

For each ownedFlowPort with direction="responds" and postCondition="Success", then the UML Operation will have return Parameters with same type as the type of the FlowPort.

All other FlowPort in the OperationPort with direction="responds" and postCondition="Success", correspond to raisedException Signal of the UML Operation. The structure of the Signal is derived from the FlowPort type: the Signal will have Attribute with same name and type of the Attribute of the type of the FlowPort.

3.6.3.11 UML Classifier represents Interface

Inheritance

N/A

Instantiation in a model

Concrete subtypes of classifier.

Semantics

The metamodel element Interface corresponds to the UML Classifier.

Foundation::Core::Classifier

A metamodel Interface can only contain metamodel OperationPort, and OperationPort can only contain constrained FlowPort.

An Classifier Classifier contains UML Operation features, corresponding to the OperationPort of the metamodel Interface.

The metamodel FlowPort, owned by OperationPort, are mapped into the UML Parameter of the UML Operation. Parameter include the return type, and alternate exceptional result types.
The metamodel FlowPort of the OperationPort must comply with constraints, ensuring that the OperationPort FlowPort can be mapped to the Parameter of the UML Operation.

The metamodel Interface can only have OperationPort and FlowPort, because only these can be mapped to UML Operation. The OperationPort and FlowPort of Interface, can only have direction="responds".

The «InitiatingRole», initiator of the Classifier, is the role that invokes operations in the Classifier. The «RespondingRole», responder of the Classifier, is the role that implements the operations in the Classifier.

### 3.6.3.13 «enumeration» DirectionKind

**Instantiation in a model**

Concrete

**Semantics**

Corresponds to the enumeration named "DirectionType" in the metamodel.

The DirectionKind enumeration in the metamodel is a UML Enumeration.

**Enumeration Literals**

Corresponding to the enumeration literals of same name in the metamodel.

Initiates

Responds

### 3.6.3.14 «enumeration» GranularityKind

**Instantiation in a model**

Concrete

**Semantics**

Corresponds to the enumeration named “GranularityKind” in the Meta-model, used by the metaattribute named "granularity", of ProcessComponent.
The set of candidate values for “granularity” in the metamodel, has been formalized in the UML Profile as an Enumeration named "GranularityKind".

Specializations of CCA may define specializations of GranularityKind with additional EnumerationLiterals.

**Enumeration Literals**
Corresponding to the enumeration literals of same name and semantics, in the metamodel.

- Program
- Owned
- Shared

### 3.6.4 Stereotypes for Choreography

**Applicable Subset**
StateMachine, CompositeState, Transition, Pseudostate, FinalState

**3.6.4.1 «Choreography»**

**Inheritance**
BehavioralElements::StateMachine::StateMachine
«Choreography»
Instantiation in a model

Concrete

Semantics

Corresponds to the element of same name in the metamodel.

Relationships

<table>
<thead>
<tr>
<th>Relationship</th>

Tagged Values

N/A

Constraints expressed generically

The context of a StateMachine stereotyped as «Choreography» will be a Classifier stereotyped as «ProcessComponent» or a Class stereotyped as «Protocol» or a Subsystem stereotyped as <<CommunityProcess>>, or their specializations.

Formal Constraints Expressed in Terms of the UML Metamodel

context Choreography

inv:
  context->notEmpty() and (
    context->isStereoKinded( «ProcessComponent») or
    context->isStereoKinded( «Protocol») or
    context->isStereoKinded( «CommunityProcess»))

Diagram Notation

N/A

3.6.4.2 «PortActivity»

Inheritance

Behavioral_Elements::State_Machines::CompositeState
  «PortActivity»

Instantiation in a model

Concrete
Semantics

Corresponds to the element of same name in the metamodel.

When a PortActivity in the metamodel references "represents" a FlowPort, then it corresponds to a «PortActivity» stereotype of CompositeState with no subvertex.

When the PortActivity in the metamodel references "represents" a MultiPort, then it corresponds to a «PortActivity» stereotype of CompositeState with subvertexes «PortActivity» corresponding to the «FlowPort» of the «MultiPort».

When the PortActivity in the metamodel references "represents" a ProtocolPort, then it corresponds to a «PortActivity» stereotype of CompositeState.

To choreograph the «Port» in the "represents" «ProtocolPort», in the context of the «PortActivity», then «PortActivity» subvertexes can be nested, corresponding to the «Port» of the «Protocol» of the "represents" «ProtocolPort».

<td>ValueFor</td>
<td>_fills</td>
</tr>
</tbody>
</table>

**Tagged Values**
N/A

**Constraints expressed generically**
If the «PropertyValue» configures the value of a «PropertyDefinition» that is the "typeProperty" of a «FlowPort», then the value configured by the «PropertyValue» must be the name of a DataType, Enumeration, «CompositeData» or «ExternalDocument».

A «PropertyValue» is an ownedElement of a «Composition» as Namespace.

**Formal Constraints Expressed in Terms of the UML Metamodel**

```uml
class PropertyValue

context PropertyValue

inv:
    namespace->notEmpty() and
    namespace.isStereoKinded("Composition")
```

**Diagram Notation**
N/A

3.6.5.6 «ContextualBinding»

**Inheritance**
Foundation::Core::Binding
«ContextualBinding»

**Instantiation in a model**
Concrete

**Semantics**
Corresponds to the element of same name in the metamodel.
A «ContextualBinding» is an ownedElement of a «Composition».
The "client" of a ContextualBinding is a «ComponentUsage» in the «Composition».
The "supplier" of a ContextualBinding is a «ProcessComponent».
In the «Composition», the «ProcessComponent» will be used as the "uses" for the «ComponentUsage».

3.6.5.7 «CommunityProcess»

**Inheritance**
ModelManagement::Subsystem
«CommunityProcess»

**Instantiation in a model**
Concrete

**Semantics**
Corresponds to the element of same name in the metamodel.
3.6.6 DocumentModel «profile» Package

The metamodel elements named Attribute, DataType and Enumeration correspond to the UML model elements of the same name and are not stereotyped.

The metaattribute named "initialValue" of the metamodel Attribute, corresponds to the attribute of same name of UML Attribute.

The metaattribute named "required" and "many" of the metamodel Attribute, are combined as a UML Multiplicity. The MultiplicityRange, will have the "lower" attribute value equal to 0, if the corresponding metamodel Attribute has the "required" meta-attribute equal to false, and greater than 0, if "required" is true. The MultiplicityRange will have the "upper" attribute value equal to 1, if the corresponding metamodel Attribute has the "many" meta-attribute equal to false, and and greater than 1, if "many" is true.

The metamodel element named Enumeration has a metaattribute named "initial" and type EnumerationValue. In the UML Profile, the responsibility of specifying an initial value, is delegated to the UML Attribute with type equal to the Enumeration. The initialValue attribute, of type Expression,  in UML Attribute will be used to specify the default initial value of Enumeration.

The metamodel element named Enumeration Value corresponds to the UML model element named EnumerationLiteral.

The metamodel Attribute and UML Attribute correspond to each other completely, with the exception of the meta-attribute named "isByValue".

To represent "isByValue", a TaggedDefinition of same name and type Boolean is defined, to be applied on UML Attribute.
The TaggedDefinition is defined without creating a Stereotype of Attribute.

**3.6.6.1 «CompositeData»**

**Inheritance**

Foundation::Core::Class

«CompositeData»

**Instantiation in a model**

Concrete

**Semantics**

Corresponds to the element of same name in the metamodel.

The «isByValue» TaggedDefinition can be applied to UML Attribute feature of «CompositeData».

**Relationships**

<table>
<thead>
<tr>
<th>Relationship</th>
<th>Role(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generalization</td>

</tbody>
</table>

**Tagged Values**

N/A
**Constraints expressed generically**

The supertype of an «CompositeData» must be a «CompositeData».

The type of Attributes of «CompositeData» will be a DataType, an Enumeration, or a Class stereotyped as «CompositeData», or a DataType stereotyped «ExternalDocument».

**Formal Constraints Expressed in Terms of the UML Metamodel**

```uml
context CompositeData
inv:
  supertype->isEmpty() or
  supertype.isStereoKinded("CompositeData")

inv:
  feature->select( aFeature : Feature | aFeature.isOCLTypeOf(Attribute))
  ->collect( aFeature : Feature | aFeature.oclAsType(Attribute).type)
  ->forAll( aClassifier : Classifier |
    aClassifier.isOclKindOf(DataType) or
    aClassifier.isOclKindOf(Enumeration) or
    aClassifier.isStereoKinded("CompositeData") or
    aClassifier.isStereoKinded("ExternalDocument"))
```

**Diagram Notation**

### 3.6.6.2 "isByValue" Tagged Definition

The metamodel Attributes and UML Attributes correspond to each other completely, with the exception of the meta-attribute named "isByValue".

To represent the metamodel attribute named "isByValue", a Tagged Definition of named "isByValue" and type Boolean is defined, to be applied on UML Attribute.

The Tagged Definition is defined without creating a Stereotype of Attribute.

3.6.7 UML Model_Management Package

There is no «profile» Package in the UML Profile for CCA, corresponding to the ModelManagement Package of the metamodel.

All the concrete metamodel elements have counterparts in UML, and therefore no stereotypes are required.

The metamodel elements named Package and ElementImport correspond to the UML model elements of the same name.

3.6.8 Relationships

This section specifies the correspondence between associations defined in the CCA Meta-model and associations defined in the UML Meta-model. The relationship name is the same as that found in the CCA Model diagrams (detail level). This correspondence is shown in the tables below, with a header for each relationship in the
metamodel. This section provides detailed information for those implementing transformations between UML and MOF CCA tools, it is not required to use or understand CCA.

How to use this section.

Each relationship between two concepts in the metamodel, or their specializations, is represented with a UML relationship(s), and in some cases as a taggedValue, or by relating through UML Association.

The tables show the Left Hand and Right Hand sides of relationships, with the role names, the actual model elements at the ends of the relationship, and the specializations or stereotypes of interest, related through the relationship - directly or by inheritance. Multiple related metamodel elements or stereotypes may appear, at any side of relationships used by multiple elements.

The semantics of each row and column in the table are

- For each relationship in the metamodel, there is one or more tables, each table showing a particular mapping for that relationship. Each table has two lines – one for the CCA model (MOF) and one for the UML model (UML)
- For each relationship mapping in the metamodel:
  - there is one row, labeled MOF, that describes the relationship in the metamodel. Its columns mean:
    - "LeftHandSide": in MOF rows, it names the MOF metamodel element that participates or inherits the relationship whose UML mapping we want to express. It may be the same as "LeftHandSide related", or a subtype of it. There may be multiple names, for various subtypes of polymorphically related metamodel elements.
    - "LeftHandSide related": in MOF rows, it names the actual metamodel element referenced by the relationship. May be the same as "LeftHandSide", or a supertype of it.
    - "LeftHandSide role name": in MOF rows, it names the relationship role on the LeftHandSide.
    - "RightHandSide role name": in MOF rows, it names the relationship role on the RightHandSide.
    - "RightHandSide related": in MOF rows it names the other actual MOF metamodel element referenced by the relationship. May be the same as 'RightHandSide", or a supertype of it.
    - "RightHandSide": in MOF rows, it names the other metamodel element that participates or inherits the relationship whose UML mapping we want to express. It may be the same as in "RightHandSide related", or a subtype of it. There may be multiple names, for various subtypes of polymorphically related metamodel elements.
  - row labeled 'UML' defining the corresponding UML Meta-model relationship. There may be additional tables for various UML mappings, describing alternative representations of the metamodel relationship in UML. The UML columns mean:
• "LeftHandSide": In UML rows, it names the UML stereotype corresponding to the LHS MOF metamodel element. There may be multiple names, for various stereotypes and specializations.
• "LeftHandSide related": In UML rows, it names the baseClass of the LHS UML stereotype, or the supertype of the baseClass, that is the actual UML model element referenced by the relationship.
• "LeftHandSide role name": in UML rows, it names the relationship role on the LeftHandSide
• "RightHandSide role name": in UML rows, it names the relationship role on the RightHandSide.
• "RightHandSide related": In UML rows, it names the baseClass of the RHS UML stereotype, or the supertype of the baseClass, that is the actual UML model element referenced by the relationship.
• "RightHandSide": In UML rows, it names the UML stereotype corresponding to the RHS MOF metamodel element. There may be multiple names, for various stereotypes and specializations.

(*) Constrained to «FlowPort». See Stereotype definitions, in sections above.

**Additional Notes:**

The MOF row is the description of the relationship in the metamodel:

The ProcessComponent, Protocol and MultiPort inherits from PortOwner, and therefore has a role 'owner' in a relationship with Port, which participates in the relationship with the role name 'ports'. Specific subtypes of Port are FlowPort, ProtocolPort, OperationPort and MultiPort, that are related with ProcessComponent through the relationship inherited from Port.

The UML row identifies the UML relationships to represent the relationship in the metamodel, above.
The stereotypes «ProcessComponent», «Protocol» and «MultiPort», corresponding to the metamodel elements of the same name, has a baseClass inheriting from Classifier, and therefore may be the participant in an AssociationEnd of a UML Association, with Classifier as the participant of the other AssociationEnd. The stereotypes with baseClass subtype of Classifier, «Port», «FlowPort», «ProtocolPort», and «MultiPort», corresponding to the metamodel elements of same name, are related with «ProcessComponent» through the said relationships with UML AssociationEnd and UML Association. MultiPort may only aggregate FlowPort.

### 3.6.8.26 Represents in Choreography

The metamodel element Choreography is represented by a UML StateMachine, where a PortActivity in the metamodel is mapped to a stereotype of CompositeState.
The Represents relationship in the metamodel, that links a PortActivity with a Port, corresponds in UML to a TaggedValue of the Stereotype «PortActivity».

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### 3.6.8.27 Represents in Composition

The metamodel element Composition is represented by a UML Collaboration.

A PortConnector is mapped to a ClassifierRole.

The "Represents" relationship linking a PortActivity with a Port, is represented in UML as a the UML relationship between a ClassifierRole and its base Classifier.

        -- with name equal to the argument as been
        -- applied to the ModelElement
        self.stereotype.name = theStereotypeName

    let isStereoKinded( theStereotypeName : String ) : Boolean =
        -- returns true if an Stereotype with its
        -- name equal to the argument, or equal to
        -- any of its inherited Stereotypes,
        -- has been applied to the ModelElement,
        self.allStereotypes->exists( aStereotype : Stereotype | aStereotype.name = theStereotypeName)
3.7 Diagramming CCA

CCA models may be diagramed using generic as well as CCA specific notations. The generic notations (as found in UML 1.4) are supported by a wide variety of tools which allow CCA concepts to be made part of the larger enterprise picture without specific tool support. When using generic notations the CCA profile stereotypes should be used. CCA aware design & implementation tools may provide the CCA specific notation in addition to or instead of the other forms of notation.

This section suggests a non-normative way to utilize generic UML diagrams and CCA notation to express CCA concepts. For the generic diagrams it does so using an “out of the box” UML tool – Rational Rose 2000e ®.

3.7.1 Types of Diagram

The diagrams used to express CCA concepts are as follows:

3.7.1.1 Class Diagrams for the Document Model
These are used to express the document model.

3.7.1.2 Class Diagrams for the Component Structure
These are used to define components & protocols, their ports and properties.

3.7.1.3 Collaboration Diagrams for Composition
These are used to express the composition of components within another component or community processes.

3.7.1.4 State or Activity Diagrams for Protocols & Process Components
These express the ordering constraints on ports within or between components.

3.7.1.5 CCA Notation for Process Component Structure & Composition
This expresses the component structure and composition in a more compact and intuitive form, thus replacing the class and collaboration diagrams. We will show how the CCA notation expresses the same concepts found in the generic diagrams.

3.7.2 The Buy/Sell Example

The techniques for diagramming CCA will be presented by example. We will utilize a simple buy/sell business process to illustrate the concepts. We will summarize the points in the specification from the perspective of using a diagramming tool.
The basic business problem of buy/sell is to define a “community process” with two actors – a buyer and seller. These two actors “collaborate” within this process to effect an order.

3.7.3 **Collaboration diagram shows community process**

At the highest level we show a collaboration diagram of the Buy/Sell community process. In the design tool we also created a package for this process to hold the relevant model elements. See Figure 3-20.

![Collaboration Diagram](image)

*Figure 3-20  Top Level Collaboration Diagram*

This collaboration shows both business roles: “Buyer” and “Seller.” These are each a “ComponentUsage” in the CCA Meta-model. It also shown that the buyer has a “buys” port and the seller has a “sells” port that are connected by a Connection in this collaboration. The “buys” and “sells” ports are “PortConnectors” in the CCA Meta-model. The line between “Buys” and “sells” indicates that the buyer and seller collaborate on these ports using a “Connection.”

There is no way to show which port is the initiator and which is the responder in a collaboration diagram, so we have noted the “buys” in blue and “sells” in green, for those of you who have color (for others you may be able to tell from the shade).

Note that “buys” and “sells” are shown inside of “buyer” and “seller”, respectively. The use of this nested classifier notation shown that the ports are owned by the component. We could have also shown the ports separately with a connected line, but nesting them seems to better reflect the underlying semantics.

The design tool we are using does not show stereotypes in a collaboration diagram, if they did show you would see that buyer and seller have the <<ComponentUsage>> stereotype and “Buys” and “Sells” have the <<PortConnector>> stereotype. You would also see that the entire package has the stereotype <<CommunityProcess>>.

The following is a summary of the elements, stereotypes and base elements you would use in a collaboration diagram for a community process:
3.7.3.1  Summary of stereotypes for a Community Process

Table 3-9  Summary of stereotypes for a Community Process

<table>
<thead>

</tr>
</tbody>
</table>

* Denotes the name used in the design tool

3.7.4 Class diagram for protocol structure

The buys and sells ports seen in the community process must have a prescribed protocol, a description of what information flows between them. This is shown in a class diagram (.). Additional information as to when information flows between them is shown on an associated state or activity diagram. The class diagram can include the definition of the data that flows between them (the document model), or this information can be shown on a separate class diagram.

This diagram shows the protocol as well as the data used in the protocol (detail suppressed for this view). The protocol is a class stereotyped as <<Protocol>>. It has a set of flow ports: SendOrder, GetConfirmation, GetDenied. Each of these flow ports has an association to the data that flows over it; Order, OrderConfirmation and OrderDenied – respectively.
A very important aspect of a port is its direction (initiates or responds), which is a
tagged value. Since these tagged values don’t show on the diagram we have also
stereotyped the relation to the ports as either <<initiates>> or <<responds>> and have
changed their color as was done in the collaboration diagram.

What this diagram shows is that implementers of the protocol “BuySellProtocol” will
receive a “SendOrder” containing an “Order” and will send out a “GetConfirmation”
(with data “OrderConfirmation”) and/or a “GetDenied” (with data “OrderDenied”).

The following is a summary of the elements, stereotypes and base elements you would
use in a collaboration diagram for a protocol:

### 3.7.4.1 Summary of stereotypes for a Protocol

*Table 3-10 Summary of stereotypes for a Protocol*

### 3.7.4.2 Summary of tagged values for a Protocol

While tagged values can’t be seen in the diagram, these elements will have tagged
values. The tagged values used to define a protocol are listed in Table 3-11.

*Table 3-11 Summary of tagged values for a Protocol*

<table>
<thead>

</tbody>
</table>
3.7.5 Activity Diagram (Choreography) for a Protocol

The class diagram for a protocol shows what the protocol will send and receive but not when. The activity diagram of the protocol adds this information by specifying when each port will perform its activity (sending and receiving information).

![Activity Diagram for a Protocol](image)

*Figure 3-22*

3.7.5.1 Choreography of a Protocol

As you can see, the activity diagram for the protocol is quite simple, it shows the start state, one activation of each port and the transitions between them. It also shows that after the “SendOrder” a choice is made and either “GetConfirmation” or “GetDenied” is activated, but not both.

The start state (Black circle) shown where the protocol will start. It then goes to a “PortActivity” for the SendOrder port (the port and the activity have the same name in this case). It then shows a choice (the diamond) and PortActivities for GetConfirmation and GetDenied ports. It then shows that either of these ends the protocol, but that GetConfirmation ends it with the status of Business Success while GetDenied ends it with BusinessFailure. (Success and failure can be tested in later transitions, using a guard on the transition). The transitions (each of the arrows) clearly shows the flow of control in the protocol.

Note that if there are multiple activities for one port it may be convenient to use swim lanes, one for each port. But swim lanes are not required.

What can not be seen is that each PortActivity has a tagged value: “represents” to connect it to the port it is an activity of. In the example “represents” will be the same as the activity name.
3.7.5.2 Summary of stereotypes for an Activity Diagram or Choreography

Table 3-12 Stereotypes for an Activity Diagram or Choreography

</tr>
</tbody>
</table>

3.7.6 Class Diagram for Component Structure

The external “contract” of a component is shown on two diagrams – the class diagram for structure and the activity diagram for Choreography (much like the protocol). The structure shows the process component(s), their ports and properties.

![Class Diagram for Component Structure](image-url)
This class diagram shows two process components being defined: “Buyer” and “Seller.” Each process component uses the “ProcessComponent” stereotype. It also shows that each of these components has one protocol port each: “Buys” and “Sells,” respectively and that both of these ProtocolPorts implement the BuySellProtocol we saw earlier.

We can also see that the buyer “initiates” the protocol via the “Buys” port and that the seller “responds” to (or implements) that interface via the “Sells” port. As before, both ports will have their direction set in a tagged value – the color and stereotypes on relations is just informational.

You may also note that we choose to define the ports as nested classes of their process components, as can be seen from the phrases (from Buyer) and (from Seller). This helps organize the classes but is purely optional.

These components are the ones we saw being used inside of the community process.

### 3.7.6.1 Summary of stereotypes for a Process Component Class Diagram

<tr>
<td>primitiveKind</td>
<td>PrimitiveKind</td>
<td>ProcessComponent</td>
<td>Buyer &amp; Seller are not primitive so have no primitiveKind.</td>
</tr>
<tr>
<td>primitiveSpec</td>
<td>PrimitiveSpec</td>
<td>ProcessComponent</td>
<td>Buyer &amp; Seller are not primitive so have no primitiveSpec</td>
</tr>
</tbody>
</table>
3.7.7 Class Diagram for Interface

Classical “services” are provided for with the CCA “Interface”, such a service interface corresponds to the normal concept of an object. An interface is a one-way version of a protocol and may not have sub-protocols. Once such service is defined for our example.

<table>
<thead>
<tr>
<th>synchronous</th>
<th>synchronous</th>
<th>FlowPort, ProtocolPort, OperationPort, MultiPort</th>
<th>All ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>transactional</td>
<td>transactional</td>
<td>FlowPort, ProtocolPort, OperationPort, MultiPort</td>
<td>True for all ports – each interaction is atomic.</td>
</tr>
<tr>
<td>direction</td>
<td>direction</td>
<td>FlowPort, ProtocolPort, OperationPort, MultiPort</td>
<td>Initiates for Buys responds for Sells</td>
</tr>
<tr>
<td>postCondition</td>
<td>postcondition</td>
<td>FlowPort, ProtocolPort, OperationPort, MultiPort</td>
<td>N/A</td>
</tr>
<tr>
<td>initial</td>
<td>None: UML “Initial Value”</td>
<td>PropertyDefinition</td>
<td>None</td>
</tr>
<tr>
<td>isLocked</td>
<td>None: UML changeability</td>
<td>PropertyDefinition</td>
<td>None</td>
</tr>
</tbody>
</table>

Table 3-15 tagged values for a Process Component Class Diagram

Since the semantics of such an interface are will understood, let’s just relate to the CCA elements:

Table 3-16 Elements of an Interface

<table>
<thead>
<tr>
<th>Example Element</th>
<th>CCA Element</th>
<th>UML Element</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustService</td>
<td>Interface</td>
<td>Interface</td>
</tr>
<tr>
<td>CheckCustomer</td>
<td>FlowPort</td>
<td>Operation</td>
</tr>
<tr>
<td>CheckCustomer. order</td>
<td>DataElement</td>
<td>Parameter</td>
</tr>
<tr>
<td>checkCredit</td>
<td>OperationPort</td>
<td>Operation</td>
</tr>
<tr>
<td>CheckCredit. amount</td>
<td>FlowPort</td>
<td>Parameter</td>
</tr>
</tbody>
</table>

Note that the use of a stereotype for an interface is optional, allowing the use of other forms of UML classifiers.

Interfaces may have the same tagged values as protocol, but interfaces don’t need “direction,” the direction is always “responds.”
3.7.7.1 Using Interfaces

While we are on the subject, let’s also look at the class diagram for a process component with a port that implements this interface.

![Diagram](image)

*Figure 3-25 Using Interfaces*

This diagram shown an “Entity” ProcessComponent (see entity profile) called “CustomerComponent” which exposes a ProtocolPort (EnqStatus) which implements this interface.
3.7.8 Class Diagram for Process Components with multiple ports

Up to this point we have seen process components with only one port, while most process components interact with multiple other components. We are going to define such a component that will be used inside other components later.

This diagram defines the OrderValidation ProcessComponent. Note that it has the following ports:

- **checkOrder** – responding flow port (the order)
- **CheckCustomer** – initiating protocol port to a service
- **AcceptOrder** – initiating flow port (the order)
- **Reject** – initiating flow port (OrderDenied)

![Figure 3-26  Process Components with multiple ports](image_url)
3.7.9 Activity Diagram showing the Choreography of a Process Component

Since our Order Validation process component has multiple ports, we may also want to specify the choreography of those ports, when each will activate. This is done using an activity diagram much like the protocol.

![Figure 3-27: Choreography of a Process Component](image)

Since the model elements used here are the same as those for the protocol, we will not repeat the tables.

3.7.10 Collaboration Diagram for Process Component Composition

A composition collaboration diagram shows how components are used to help define and (perhaps) implement another component. We have already seen one composition, for the community process. Now we will look at a collaboration diagram which specifies the inside of one of our process components – the seller.
This is a collaboration diagram “inside” the seller, which the seller will do to implement its protocol by using other components. This is a very specific use of a collaboration diagram and needs some explanation.

First note that, like the community process, we are showing the ports of components and of protocols nested inside the component or protocol.

The Component Usages are as follows:
- Validate – uses the “OrderValidation” component
- CustBean – uses the CustomerComponent
- Process – uses the “OrderProcessing” component (not previously shown)

If we look inside of “Validate” we see a classifier role for each port: checkOrder, reject, CheckCustomer & acceptOrder. We see the same pattern repeated inside of CustBean and Process.

Note – “Seller : Sells” - This is the representation of the “Sells” port on the component being defined – in this case “Seller.” There will be such a “proxy” PortConnector for each port on the outside of the component for which we are making the collaboration diagram. Since this port is a protocol port, it also has sub-ports which show up as nested classifier roles.
To “connect” one port to another we draw an association role (a line representing a Connection) from one port to another. The connected ports must have compatible types and directions. So in this diagram we have made the following connections:

### 3.7.10.1 Connections in the example

<table>
<thead>
<tr>
<th>From Component Usage</th>
<th>From Port Connector</th>
<th>To Port Connector</th>
<th>To Component Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seller</td>
<td>Sells</td>
<td>CheckOrder</td>
<td>Validate</td>
</tr>
<tr>
<td>CheckOrder</td>
<td>Reject</td>
<td>GetDenied</td>
<td>Seller</td>
</tr>
<tr>
<td>Validate</td>
<td>CheckCustomer</td>
<td>EnqStatus * Using Operation “checkCust”</td>
<td>CustBean</td>
</tr>
<tr>
<td>Validate</td>
<td>AcceptOrder</td>
<td>DoOrder</td>
<td>Process</td>
</tr>
<tr>
<td>Process</td>
<td>ProcessOrder</td>
<td>GetConfirmation</td>
<td>Seller</td>
</tr>
</tbody>
</table>

Each of these connections will cause data to flow from one component to the other, via the selected ports. It is these Connections which connect the activities of the components together in the context of this composition.

### 3.7.10.2 Summary of stereotypes for a Process Component Collaboration

<table>
<thead>
<tr>
<th>CCA element</th>
<th>Stereotype</th>
<th>Base UML Element</th>
<th>Example Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Composition</td>
<td>&lt;&lt;Composition&gt;&gt;</td>

</tr>
<tr>
<td>ContextualBinding</td>
<td>&lt;&lt;ContextualBinding&gt;&gt;</td>
<td>Binding (Note*)</td>
<td>None – used to refine which component type to use</td>
</tr>
<tr>
<td>PropertyValue</td>
<td>&lt;&lt;PropertyValue&gt;&gt;</td>
<td>Constraint (Note*)</td>
<td>None – use to set a configuration property of a component</td>
</tr>
</tbody>
</table>

### 3.7.10.3 Special note on “proxy” port activities.

As can be seen from the example, we need to connect the “outside” ports (those on the component being defined) with the “inside” ports (those on the components being used). The PortConnectors for the outside ports are shown without an owning ComponentUsage, while the PortConnectors for the components being used are shown inside of the ComponentUsage being used.
3.7.10.4  Special note on protocols

Since protocols give us the ability to “nest” ports, ports may be seen within ports to any level. This example only shown one level of such nesting. The same kind of nesting is used within activity diagrams – since activities may be nested as well.

3.7.11 Model Management

While the organizational structure of components is not visible in a diagram, it is visible in tools. The screen shot in shows how the example components are organized in the Data Access Technologies’ UML tool. Note how using nested classes (such as Ports being inside of their ProcessComponent) helps to organize the model and keep namespaces separate.
Figure 3-29  Model Management
3.7.12 Using the CCA Notation for Component & Protocol Structure

Figure x-x shows the CCA notation being used for the protocol and process component structure, above. Note that as with the UML notation, this is done from an out-of-the-box tool (Component-X®) - the notation is not quite standard CCA yet.

This shows the community process and protocol corresponding to the UML example, above.

![Figure 3-30 Community Process and Protocol](image)

![Figure 3-31 Composition in CCA notation](image)

Figure 3-31 shows the seller composition in CCA notation; it is equivalent to the seller collaboration diagram.
Section III - The Entities Profile

The Entities profile describes a set of UML extensions that may be used to model entity objects that are representations of concepts in the application problem domain and define them as composable components.

Section 3.8 introduces the profile and concepts associated with it. Section 3.9 describes different entity viewpoints. Section 3.10 presents the Entity conceptual metamodel. Section 3.11 defines the UML extensions required to implement the Entity metamodel as a UML profile.

3.8 Introduction

This section describes the following:
• Normative sections of this section
• The Entities profile relationship to other profiles
• The design concepts incorporated in the Entities profile
• Standard UML facilities incorporated in this profile

3.8.1 Normative sections

Section 3.8 to Section 3.11 of this chapter should be viewed as the adopted specification. Of those sections, only Section 3.10 and Section 3.11 are normative. The other sections provide an introduction to the chapter and a conceptual background.

3.8.2 Relationship to other parts of ECA

The following paragraphs briefly describe the links to other profiles in the ECA specification.

3.8.2.1 The Business Process profile

The Entities profile is used to define a representation of the application domain. Processes operate on this model where the process flow determines that operations should occur on the domain model as a result of inputs from other systems, the occurrence of business events or the actions of human participants.

The Entities profile also provides a root modeling element for identifiable processes. In a business domain a process is also an identifiable concept that has instances with attributes, operations and relationships. As such, it shares the characteristics of Entity objects and can be operated on the same as entities. A process could be the subject matter of another process.
3.8.2.2 The CCA profile

Elements of the Entities profile are also characterized as composed components that can be composed into larger components. As components they may be made available for composition of a variety of systems. As composed components, they may be configured from independently created components. The component profile determines the unit of composition and the interconnection of interfaces that enables the components to work together.

3.8.2.3 The Events profile

The event profile defines the integration of systems and components using events to drive the processing. Events may be published or received by entities and processes. Events may be forwarded synchronously or asynchronously. Synchronous events will typically be delivered within the context of the current transaction. Asynchronous events will generally be stored and delivered in the context of a new transaction. The use of events for integration reduces coupling and improves the ease by which a system may be adapted or extended.

The Entities profile recognizes the publish and subscribe ports as elements that may be attached to entity components. In addition, it defines the Data Probe port to generate events requested on an ad hoc basis.

3.8.2.4 The Relationships profile

Entities have relationships. Relationships represent associations between the real-world counterparts of domain model elements. The variety of relationships is defined by the Relationship Profile.

3.8.2.5 The Patterns profile

Patterns may be used to replicate frequently occurring entity structures including attributes, relationships, operations, rules, and constraints.

3.8.3 Design Concepts

The entity model reflects the integration of a number of design concepts:

- Composition
- Encapsulation
- Ports
- Identity
- Events
- Domain Modeling
- Entity Role
- Events
3.8.3.1 Composition

Entities are representations of concepts that exist in the real world or application problem domain. The primary purpose of the entity profile is to model entities—their relationships, attributes and methods—and define them as composable components.

The information viewpoint will provide the primary notation for modeling entities and their attributes and relationships as data. The entities represented in the information viewpoint are then incorporated into objects, described as composable components.

Entities are incorporated into systems where they may be acted upon by processes, interact with other entities and generate events. Thus entities are components in a larger system. The component relationships of entities to other components is expressed in the composition viewpoint. In this viewpoint entities are components that are composed into larger components.

As a component, an entity may have several different ports. It receives and responds to messages. It may send messages and receive return values, it may generate events or asynchronous messages and it may receive events or asynchronous messages. In addition, it may accept ad hoc requests to generate messages based on changes in its state.

Entities that represent primary concepts, such as Customer, will often be composed with related entities and value objects as deployable components. So the Customer and Account entities could be composed into one component also containing the Customer Address and Account Entry value objects.

3.8.3.2 Encapsulation

Entity components are intended to be encapsulations of their associated data and functionality. Process Component defined in the CCA specification provides the basic representation of encapsulation. It provides the external interfaces by which these components are linked to other components and composed into larger components. At the same time, it does not define the component implementation.

Data Manager extends this by incorporating Composite Data. Consequently, a data manager contains composite data that describes the state of the component. Data Manager incorporates the composite data and relationships of Entity Data along with methods to operate on the data.

A Data Manager may be implemented as an object. The object has an interface, modeled as a component port, and it has state data that may be accessed through the port. The object may also have other ports. It may have data probe ports to generate
messages based on ad hoc requests. It may send asynchronous messages and events.
If it has a unique identity (i.e., is an Entity), and is sharable and network accessible, it
can receive asynchronous messages and events.

Data Manager comprehends value objects, objects that are passed by value, i.e., by
copying the data, not by reference. Consequently, the data structure is exposed when a
copy is performed. It is important to distinguish between the value object that has a
functional interface, and the state of the value object, the Entity Data, which is passed
when a value object is passed as a parameter.

Value objects are not sharable nor network accessible. They cannot receive messages
over the network, and they are not sharable because they are always passed by value
rather than by reference.

Data Managers may be network accessible or not. A Data Manager may be only
accessible by reference to a related entity that is network accessible. For example, a
order line item is identifiable but may only be accessible through the order.

An Entity may be a copy of a primary Entity, i.e., a clone, for purposes of improving
performance. An Entity clone may be a copy of an entity on a client system that is used
for interactive operations. Or the clone could be the instantiation of an entity when
concurrency control is performed by a database (i.e., the primary entity is in the
database). The clone is instantiated with a copy of the entity’s state. The primary
Entity should be locked when the copy is taken so that it’s state will not change while
operations are being performed on the clone. The clone is not sharable because it
should not exist beyond the transaction in which it was created. Its lock on the
primary entity will expire when its transaction terminates.

3.8.3.3 Ports

Components interact with their environment through ports. A port has a defined
interaction protocol. Ports may send messages, receive messages, or both. A port may
be implemented as an object interface, e.g., CORBA or Java interface.

Ports are synchronous or asynchronous. A synchronous port communicates within the
context of a transaction. An asynchronous port communicates in a store-and-forward
manner so that sending a message occurs in the context of one transaction and receipt
of the message then occurs in the context of another transaction.

Ports may communicate with messages or event notices. A message is directed to a
specific destination. An event notice is published to the communication infrastructure
to be delivered to subscribers—destinations that have expressed interest. The messages
and event notices may be communicated synchronously or asynchronously.

All Data Managers will have interface port(s) that represents the interface of the
component; these ports may be synchronous, asynchronous or a combination of both.

3.8.3.4 Identity

Unique identity is introduced on Entity Data and implicitly on Entity with the addition
of a Key. A prime key is required to be unique within the extent of the type. In
general, identifiable components are passed by reference.
The key may be comprised of one or more attributes of the state of the component, and these elements must be immutable. The key can also have elements that are Foreign Keys of other Entities. A Foreign Key is identified through a relationship with another Entity from which the Foreign Key is derived.

An Entity component has a primary instance, i.e., the location of the master copy of its state. This master copy may be in a database or it may be instantiated as an object/component. Copies of an Entity state may be instantiated in Entity clones. These are not sharable and, in general, should not exist beyond the scope of a single transaction.

Entity components can be “managed.” This property specifies that the extent of all members of a type and its sub-types is known and may be accessed as a set. The key of an identifiable component must be unique within its managed extent. The implementation implication of being managed is that the type will have an extent manager or “home” that will provide query access to the extent and may provide attributes and methods that apply to all members of the extent or the members collectively, e.g., the number of members.

### 3.8.3.5 Domain Modeling

The first step in modeling a business domain may be to create an information viewpoint. The information viewpoint exposes the Entity Data along with its attributes and relationships. These Entity Data elements will be incorporated into Entity components to define their functionality and interfaces.

In modeling a business domain, business concepts that are uniquely identifiable must be represented by identifiable computational components. For example, an object representing an employee, a purchase order, an office or a part specification will have a unique identifier that associates the object with the real-world counterpart. As such, a consistent representation of the business will have a single representation of each real-world thing as an identifiable object. While an implementation may replicate such elements for performance or reliability, replicas are still logically a single representation and must be maintained with consistent state if the system is to yield consistent results.

For the most part, the identifiable elements that model the business domain are characterized as Entities. Rules and Processes are also Entities because they have state and are identifiable, but they are computational artifacts that describe activities in which entities are involved.

### 3.8.3.6 Entity Role

The Entity Role is an important extension to the Entity representation. It may be impractical to design an Entity component to anticipate all circumstances in which an entity may be involved. Each situation may involve different state and behavior. An Entity Role incorporates aspects of an Entity associated with a particular context. It essentially extends an Entity on an ad hoc basis. The unique identity of an Entity Role is the entity identifier coupled with its context identifier. Consequently, the context must also be represented as an Entity component. For example, a person has the role
of an employee as a member of an enterprise (context), or may be a member of a project team. An entity may have many roles as appropriate to the different contexts in which it participates.

An Entity Role is dependent upon the associated parent entity. The association is immutable. If an Entity ceases to exist, all of its roles will also cease to exist. An Entity Role cannot be assigned to another parent Entity.

An Entity Role is not an appropriate representation for such concepts as an organizational position or the specification of a process participant. These concepts may define characteristics of the entities that can be assigned, but should not include characteristics that are unique to a particular Entity when assigned. Consequently, a process participant is an Entity that represents a potential association of a process with an Entity. Different Entities may be assigned to the participation over time. An Entity Role may be assigned to the participation, as an employee may be assigned to participate in a process, and a different employee may be substituted at a later time.

An Entity Role may be a “virtual entity” if it incorporates all of the interface characteristics of the entity it represents. For example, an Entity Role may inherit the interface of its associated Entity, incorporate the interface by inheritance and incorporate the entity state and behavior by delegation.

3.8.3.7 Events

An event represents a change of state in a system that is of interest outside the scope of the component in which it occurs. An event may be defined as a change of state that causes a condition of interest to become true, or an event may be associated with a state transition to a particular state, from a particular state, or from one state to another state. When an event occurs a notice can be generated.

The ability to generate event notices can be designed into a component. The content of the event notice is defined to provide appropriate information about the event. Event notices are published—they are issued to the event communication infrastructure to be received by subscribers. The publisher of an event notice is not expected to be aware of the subscribers, and thus there may be many subscribers or none. Similarly, the subscribers are not aware of the specific sources of event notices to which they subscribe.

The Event Publication and Event Subscription ports provide the complementary interfaces for this publish and subscribe linkage between components. These ports may be defined as operating in synchronous or asynchronous mode.

The mode of a subscriber must match the mode of the receiver for an event notice to be communicated. In synchronous mode, an event notice would be delivered to all subscribers within the context of the transaction in which the event occurred. In asynchronous mode, the event would be delivered in a store-and-forward manner, the event notice would be captured in one transaction and accepted by each subscriber in different transactions.
3.8.3.8 Data Monitoring

Data monitoring refers to the ability to ad hoc initiate detection of changes in data in order to initiate desired actions. This capability is an important element of flexibility and modularity of system design. It allows actions to be initiated based on changes in state without explicitly embedding the initiation of those actions in the executable logic that changes the data.

For example, an application may be designed to monitor the price of a commodity to initiate buy or sell orders or alert a customer. It should not be necessary to modify the logic of the commodity tracking system in order to link this monitoring application to price changes.

Similarly, when a system is assembled or extended using components, actions of some components may be dependent on changes in state in other components. By providing the ability to monitor changes in the data of a component, the logic of the component need not be designed to anticipate each specific dependence.

The Data Probe port provides the interface for accepting and removing monitoring requests and for issuing events or messages when the specified events occur in the state of the Entity. A request will defines the state of interest, the type of message to be sent and the message addressee.

3.8.3.9 Distributed Computing

Components that are remotely accessible must be identifiable. Their unique identity is the basis for locating them in the distributed computing environment. It is also the basis for sharing a single representation of the state of the thing being represented.

To support network access, they must have one or more ports that support network access protocols. For example, a network accessible component might have ports synchronous messaging ports implemented as CORBA interfaces, and event subscription and publication ports implemented as JMS (Java Messaging Service) subscriber and publisher interfaces.

Data Managers that are not network accessible will be restricted to being co-located with components that reference them. For example, an order item is uniquely identified within an order, but remote access may be only through interfaces to the containing order.

Relationships require that the participating Entity Data structures are identifiable. At the same time, the Data Manager of an Entity Data structure may not be network accessible. In a distributed computing environment, components that participate in relationships must be either co-located or be network accessible. A relationship cannot be implemented if the members cannot communicate with each other.

While distribution of computing is primarily an implementation issue, the ability for components to be distributed must be considered fairly early in the design. Where Entity components are not network accessible, operations on their containing components will likely reflect indirect access from remote components.
3.8.3.10 Levels of Coupling

The Entity Model anticipates three levels of component coupling: *linked, tightly coupled* and *loosely coupled*.

Linked coupling refers to components that are co-located in the same address space. These components interact with each other directly, without communicating over a network. As such, they can interact without being network accessible components. Messaging will generally be synchronous, within the scope of a single transaction.

Tightly coupled components are distributed across multiple servers. These components will also interact with synchronous messaging, but messaging will occur over a network. While some messaging between the components may be asynchronous for performance and recoverability considerations, components are tightly coupled if any interactions between them are synchronous.

Loosely coupled components are distributed and only communicate asynchronously, through a messaging infrastructure. Communication is through messages and events. These components might be characterized as enterprise applications. A message or event is issued in the scope of one transaction and accepted by one or more recipients in independent transactions. Messages and events are stored and forwarded. A message is a communicated with a defined recipient, and an event is a communicated (published) with self-declaring recipients (subscribers) unknown to the publisher.

The level of coupling between components has important performance and system flexibility implications. Generally, components should be designed in a level-of-coupling hierarchy so that components that are linked are within components that are tightly coupled, and tightly coupled components are within components that are loosely coupled with each other. This coupling hierarchy should be reflected in the network accessibility property of components and the synchronous vs. asynchronous property of their ports.

3.8.4 Standard UML Facilities

This section briefly describes the standard elements of UML that are incorporated in the profile.

Attributes

Composite Data elements define their data elements with attributes. Composite Data elements are incorporated as the data structures of Data Managers, which are specialized to entities. The interfaces to Data Managers provide access to the attributes and will generally have methods by the same name as accessers.

Methods

Methods are specified as in UML. From a component perspective, methods, including the attribute accesser methods, are incorporated in the port(s) which receive messages and return a result.
Relationships

Relationships express associations between non-primitive elements. Identifiable, sharable and network accessible elements can have relationships that extend over a distributed network.

Activity Graphs

Activity Graphs may be used to describe flow of control between elements, although these will be more applicable for describing processes.

State Machines

Changes of state of elements with data may be described with state machines. Publication of events may be defined in terms of state transitions.

Interaction diagrams

Interaction diagrams may be used to describe the flow of control between executable elements.

Object Constraint Language

OCL is used to express conditions for triggers, as well as in other applicable UML elements.

3.9 Entity Viewpoints

The entity profile provides elements that appear in different viewpoints. These viewpoints are for different purposes and represent entities differently, using different forms of notation. Two viewpoints of particular interest are presented below: the information viewpoint and the composition viewpoint. Entities also appear in other diagrams, for example, in interaction diagrams as vertical lines and in activity diagrams as swim lanes.

3.9.1 Information Viewpoint

The information viewpoint models Entity Data and their relationships. Entities represent concepts in the problem domain, and relationships represent relationships between the problem domain concepts. The model essentially defines the vocabulary used in discussing the problem domain, and it represents the structure of the objects and databases used to represent the business concepts in the computer.

A model viewed from the information viewpoint is shown below. It includes four Entities: Customer, Address, Account, and Entry. Each of these can be uniquely identified, but Address and Entry are unique within the contexts of Customer and
Account, respectively. Consequently, as components, Address and Entry may be specified as not sharable or network accessible. They would be implemented as pass-by-value objects.

![Entity Model in the Information Viewpoint](image)

The information viewpoint says nothing about interfaces or object-oriented functionality that may be associated with these Entities. Nor does it define how these objects might be packaged in a composed system. Those aspects are defined by the Entity components that incorporate the Entity Data.

### 3.9.2 Composition viewpoint

The composition viewpoint describes how the software artifacts are configured as components and compositions of components. The diagram below depicts an Account Composition component, which is composed of Account Entity and Entry Entity components.

![Entity Model in the Composition Viewpoint](image)
The Account entity may request attribute values from the Entry object, or, assuming the Entry object is a pass-by-value object, it may pass the Entry object by value. This means it passes a copy of the state of the Entry object, but it retains its reference to the original Entry object for future operations.

The Account and Entry objects are both components used to compose the AccountComponent. However, this could be simply the logical model of the composition. The implementation of the AccountComponent might be primitive, making the Account and Entry objects inseparable, but logically independent.

The ports in this model are interface ports and message-sending ports—they incorporate synchronous messages, typical of messaging with objects. The AccountComposition component may or may not expose the same interfaces as the Account component. It also could expose an interface for the Entry component, but none is specified here.

The composition viewpoint drives consideration of network accessibility and the clustering of objects for composition and distribution.

### 3.10 Entity Metamodel

This section describes the entity meta-model. This model provides a basis for understanding the modeling concepts and their relationships. The next section describes the implementation of the model in UML.

#### 3.10.1 Overview

The diagram, below, depicts the elements to be considered; those that are part of this profile specification are highlighted. Central to this model are Data Manager and its specializations; these are the core elements of the Entities profile. They encapsulate data and other components, exposing their functionality through ports.
3.10.2 Entity Package

This section describes the elements of the Entity metamodel in detail.
3.10.2.1 Data Manager

Semantics
A Data Manager is a functional component that provides access to and may perform operations on its associated Composite Data (i.e., its state).
The Data Manager defines ports for access to operations on the state data.

UML base element(s) in the Profile
Class

Fully Scoped name
EDOC::ECA::Entity::Data Manager

Owned by
Package

Properties

Network Access
A Boolean value which indicates if the Data Manager is intended to be accessible over the network.

Sharable
A Boolean value which indicates if the Data Manager can be shared by multiple transactions/sessions. A Data Manager that is not sharable is either transient or depends on a sharable Data Manager that contains it for persistence. For example, an address may not be sharable (although its state may be passed by value), but it can be persistent by association with a Customer that is sharable.

Related elements

Process Component
Data Manager inherits from Process Component and adds the quality of having associated state.

Composite Data
Composite Data defines the data structure that is encapsulated by the Data Manager.

Entity
Entity specializes Data Manager for representation of identifiable application domain things.
Constraints
N/A

3.10.2.2 EntityData

Semantics
Entity Data is the data structure that represents a concept in the business domain. It is equivalent to an entity in data modeling or a relation in a relational database. In a Data Manager or its specializations, such as Entity, it represents the state of an object.

Entity Data has attributes (from Data Element) and relationships. The information viewpoint is a viewpoint on Entity Data elements.

UML base element(s) in the Profile
Class

Fully Scoped name
EDOC::ECA::Entity::EntityData

Owned by
Package

Properties
N/A

Related elements

Composite Data
Entity Data inherits from Composite Data and adds relationships.

Relationship
Describes an association between Entity Data elements.

Data Manager
A Entity Data element is incorporated in a Data Manager which gives it functionality and ports as a component.

Constraints
- Entity Data must have a prime Key that is unique within the extent of the Entity Data type (i.e., the type and all sub-types).
- Entity Data is managed by an Entity Data Manager.
3.10.2.3 Key

**Semantics**

A Key is a value that may be used to identify a Data Entity for some purpose. Generally, it will be a unique identifier within some context. A Key designated Prime Key = true is the key intended for unique identity of the Data Entity within the extent of the Data Entity type.

A Key is composed of key elements which may be selected attribute values of the associated Data Entity or Foreign Keys. A Foreign Key is the key of a related Date Entity.

**UML base element(s) in the Profile**

Class

**Fully Scoped name**

EDOC::ECA::Entity::Key

**Owned by**

Entity Data

**Properties**

*Prime Key*

A Boolean value that indicates if the Key is intended to be the primary unique identity of the associated Entity Data type. If so, the value must be unique within the extent of the identifiable type.

**Related elements**

*Composite Data*

A Key is a specialization of Composite Data.

*Entity Data*

A Key describes an identifier of an Entity Data type.

*Key Element*

A Key Element is one segment of a Key, which is either a reference to an attribute of the associated Data Entity or a reference to the key of an associated Data Entity.

**Constraints**

- If Key is Prime Key = true, then the value must be unique within the extent of the associated Entity Data type and its sub-types.
The attributes that are incorporated into the key must be immutable.

The Key Elements that comprise the key have an immutable sequence.

3.10.2.4 Key Element

Semantics
A Key Element is one segment of a Key, which is either a reference to an attribute of
the associated Data Entity or a reference to the key of an associated Data Entity.

UML base element(s) in the Profile
Class

Fully Scoped name
EDOC::ECA::Entity::Key Element

Owned by
Key

Properties
N/A

Related elements
Key
The Key in which the Key Element appears.

Key Attribute
A Specialization of Key Element that references an attribute in the associated Entity Data..

Foreign Key
A specialization of Key Element that references the Key of an Entity Data structure
that is related to the Entity Data identified by the containing Key.

Constraints
N/A
3.10.2.5 Foreign Key

Semantics
A Foreign Key is a Key Element that is the value of a related Entity Data structure. The subject Entity Data structure derives its identity, in part, from the related Entity Data structure. For example, the line item of an order may be uniquely identified by the line number and the key of the associated order. The Foreign Key element references the relationship in order to identify the related Entity Data that contains the Foreign Key value.

UML base element(s) in the Profile
Class

Fully Scoped name
EDOC::ECA::Entity::Foreign Key

Owned by
Key

Properties
N/A.

Related elements
Key Element
Foreign Key is a specialization of Key Element.

Relationship
The associated relationship identifies the Entity Data from which the Foreign Key value is obtained..

Constraints
• If the associated Key has PrimeKey = true, then the relationship used to obtain the Foreign Key value must be immutable.

3.10.2.6 Key Attribute

Semantics
A Key Attribute identifies an attribute of the associated Entity Data that is included as an element of the Entity Data key. The value of the attribute becomes an element of the key of an instance of the Entity Data type.
### UML base element(s) in the Profile

Class

### Fully Scoped name

EDOC::ECA::Entity::Key Attribute

### Owned by

Key

### Properties

N/A.

### Related elements

**Key Element**

Key Attribute inherits from Key Element.

**Attribute**

Attribute is the Attribute of the Entity Data structure that is to be incorporated as an element of the containing Key.

### Constraints

If the containing Key is designated PrimeKey = true, then the Attribute values that are incorporated into the key must be immutable.

#### 3.10.2.7 Entity

### Semantics

An Entity is an object representing something in the real world of the application domain. It incorporates Entity Data that represents the state of the real world thing, and it provides the functionality to encapsulate the Entity Data and provide associated business logic.

An Entity instance has identity derived from the Key of its associated Entity Data.

Entity is the abstract super type of all identifiable application domain elements. This includes Entities that have a collection of rules to operate on the state of related entities. It also includes Entities that incorporate process elements that act on other Entities. The rule set and process specializations introduce additional elements, but have the basic characteristics of being identifiable, having local state (Composite Data) often viewed as their “context,” and having relationships to other Entities that they may act upon.
If an Entity is managed, all instances of the type and its sub-types are known, each instance has unique identity, and the type can have operations and attributes associated with the extent (i.e., applicable to all instances). This is typically implemented as a type manager or “home” object that represents the extent.

**UML base element(s) in the Profile**

Class

**FullyScoped name**

EDOC::ECA::Entity::Entity

**Owned by**

Package

**Properties**

In the list, below, only Managed is introduced as a property by Entity, but NetworkAccessible and Sharable, inherited from Data Manager, are also discussed to clarify the implications.

**Managed**

A Boolean value that indicates if the Entity type is managed. If it is managed, then the implementation provides a mechanism for accessing the extent of all instances of the type and its sub-types and may provide a mechanism for dynamically applying rules to all instances. This typically is implemented as a “home” or “type manager.”

**NetworkAccessible**

A Boolean value that indicates if the Entity is expected to be accessed over the network. This implies that it has a network interface (e.g., CORBA IDL). An Entity that is not NetworkAccessible can only be accessed over the network through an associated Entity that is NetworkAccessible.

**Sharable**

A Boolean value that indicates if the Entity can be shared by multiple, concurrent transactions or users. A Sharable Entity will enforce controls to serialize access by concurrent transactions.

An Entity that is not sharable may be instantiated for use by a particular user or transaction. It generally contains a copy of the primary Entity Data instance representing the real world thing. The primary Entity Data instance may be in a database and the copy is created to perform operations on the Entity Data. Alternatively, the Entity Data may be managed by an Entity that is sharable, but the copy is created so that processing can be localized on another server. In either case, it would be expected that the primary Entity Data would be locked when the copy is taken and released when the copy is deleted. Changes to the copy would likely be applied to the primary instance prior to removing the lock.
Entities that are not sharable may also be implemented as value objects, which are always passed by value over the network. While they may have unique identity by association with an identifiable Entity, they may not have a key that reflects this unique identity and their Entity Data does not carry its unique identity when passed by value.

An Entity that is sharable is expected to be persistent. An Entity that is not sharable may be persistent if it is incorporated in the state of a sharable Entity.

**Related elements**

*DataManager*

Entity inherits from DataManager and adds the requirement that its associated Composite Data is Entity Data. It also adds the ability to accept Data Probes and the ability to be Managed.

*Entity Role*

Entity Role inherits from Entity as a specialized representation of an Entity in a particular context. The Entity Role contains Entity Data that is associated with the parent Entity in the particular context. Entity Role is associated with another Entity that represents the context in which it applies. Thus the parent Entity might be a person, the Entity Role might be the person as an employee, and the context entity might be the employer.

An Entity may have many Entity Roles. Each Entity Role defines characteristics of the Entity in a particular context, such as person in the role of an employee within a corporation. An Entity may be the context for many Role Entities as a corporation is the context of many employees.

*Data Probe*

A Data Probe port is associated with an Entity that accepts requests to detect changes in the internal state of the Entity and forwards messages or events when the states of interest become true.

**Constraints**

- An Entity manages Entity Data, which may have a key and relationships.
- A managed Entity must have a Primary Key.
- A network Accessible Entity must have a Primary Key
- An Entity that is Sharable will serialize concurrent transactions that attempt to access its data.
3.10.2.8 Entity Role

Semantics
An Entity Role extends its parent Entity for participation in a particular context. An Entity may have a number of associated Entity Roles reflecting participation in multiple contexts. The Entity might have several Entity Roles of the same type at the same time, but each should be associated with a different context.

The context of an Entity Role is also represented by an Entity. The context could be a corporation where the parent is a person and the Entity Role is an employee. A context may have many entity roles of the same type or different types representing participation of different parent Entities for different purposes.

UML base element(s) in the Profile
Class

Fully Scoped name
EDOC::ECA::Entity::Entity Role

Owned by
Entity (context)

Properties

VirtualEntity
A Boolean value that indicates if the Entity Role incorporates and extends the primary interface of the parent Entity it represents, i.e., it can be used in place of the primary Entity.

Related elements

Entity
• Inheritance—Entity Role inherits from Entity such that it functions as an entity but it derives its unique identity from the Entity it represents (i.e., a Foreign Key).
• Context association—An Entity Role represents an Entity in a particular context. This association defines the context.
• Parent association—An Entity Role represents an entity in a particular context. This association defines the parent Entity being represented.

Constraints
The parent entity of an entity role cannot be dynamically changed.
3.10.2.9 **DataProbe**

**Semantics**

A Data Probe port is associated with an Entity and accepts ad hoc requests to detect changes in the internal state of the Entity. The Data Probe then forwards messages or events when the states of interest become true until the request is removed. A Data Probe may serve many requests concurrently, producing various messages or events when the appropriate states occur.

**UML base element(s) in the Profile**

Class

**Fully Scoped name**

EDOC::ECA::Entity::Data Probe

**Owned by**

Entity

**Properties**

*ExtentProbe*

ExtentProbe = true indicates that requests apply to the extent of the associated entity as opposed to a particular instance. In implementation, an ExtentProbe would be associated with a “home” or “type manager.”

**Related elements**

*Multi Port*

Data Probe inherits from Multi Port.

*Entity*

The Entity that will accept probe requests.

**Constraints**

- DataProbes only emit messages (i.e., output only).
- DataProbe can only attach to an Entity with Managed = true.

### 3.11 Entity UML Profile

This section specifies the entity model as a UML profile. The profile consists of standard UML facilities with the addition of a number of extensions specified in terms of stereotypes, tagged values and constraints.
The section begins with a table that maps the conceptual metamodel elements to the UML elements, and then describes the UML package and the UML extensions in detail.

3.11.1 Metamodel Mapping to Profile

Table 3-19 provides a mapping of metamodel elements to UML profile elements.

3.11.2 Entity Package

Figure 3-35 illustrates the extensions required for the entity model and the relationships of these extensions to elements described in other ECA models. The extensions shown in this diagram are discussed in the paragraphs that follow.
3.11.2.1 Data Manager

Inheritance

Class

Process Component
Data Manager

Instantiation in model

Concrete
Semantics
A data manager is a functional component that provides access to and may perform operations on its associated Composite Data (i.e., its state). Since, without specialization, it is not uniquely identifiable it would be expected to get its identity from a context, i.e., it may be embedded in another component or it could exist only for a particular session.

Tagged values

Network Access
A Boolean property that expresses whether the implementation would be expected to have a network accessible interface.

Sharable
A Boolean property that indicates if the implementation can be shared across multiple sessions and/or in by concurrent transactions.

Manages
A reference to the associated Composite Data specification.

Constraints
N/A

Diagram notation
Equivalent to Class

3.11.2.2 Entity Data

Inheritance
Class

  Composite Data

  Entity Data

Instantiation in a model
Concrete

Semantics
Entity Data is the data structure that represents a concept in the business domain. It is equivalent to an entity in data modeling or a relation in a relational database. In a Data Manager or its specializations, such as Entity, it represents the state of an object.
Entity Data has attributes (from Data Element) and relationships. The information viewpoint is a viewpoint on Entity Data elements.

**Tagged values**

*Key*

A reference to the associated Key specification(s).

**Constraints**

- Entity Data must have a prime Key that is unique within the extent of the Entity Data type (i.e., the type and all sub-types).
- Entity Data is managed by an Entity Data Manager.

**Diagram notation**

None

### 3.11.2.3 Key

#### Inheritance

Class

Composite Data

Key

#### Instantiation in a model

Concrete

#### Semantics

A Key is a value that may be used to identify a Data Entity for some purpose. Generally, it will be a unique identifier within some context. A Key designated Prime Key = true is the key intended for unique identity of the Data Entity within the extent of the Data Entity type.

A Key is composed of key elements which may be selected attribute values of the associated Data Entity or Foreign Keys. A Foreign Key is the key of a related Date Entity.

**Tagged values**

*Prime Key*

A Boolean value that indicates if the Key is intended to be the primary unique identity of the associated Entity Data type. If so, the value must be unique within the extent of the identifiable type.
Key Elements
A list of key elements consisting of references to attributes and relationships of the associated Entity Data.

Constraints
- If Key is Prime Key = true, then the value must be unique within the extent of the associated Entity Data type and its sub-types.
- The attributes that are incorporated into the key must be immutable.
- The Key Elements that comprise the key have an immutable sequence.

Diagram notation

3.11.2.5 Foreign Key

Inheritance
Attribute
Key Element
Foreign Key

*Instantiation in a model*

Concrete

*Semantics*

A Foreign Key is a Key Element that contains a reference to a related Entity Data structure. The subject Entity Data structure derives its identity, in part, from the prime key of the related Entity Data structure. For example, the line item of an order may be uniquely identified by the line number and the key of the associated order. The Foreign Key element references the relationship in order to identify the related Entity Data that contains the Foreign Key value.

*Tagged values*

*KeySource*

A reference to the relationship through which the value and structure of the foreign key are derived.

*Constraints*

- The related Entity Data must have a prime key.
- If the containing Key is designated PrimeKey = true, then the relationship for the KeySource must be immutable.

*Diagram notation*

Attribute

3.11.2.6 *Key Attribute*

*Inheritance*

Attribute

- Key Element
  - Key Attribute

*Instantiation in a model*

Concrete

*Semantics*

A Key Attribute identifies an attribute of the associated Entity Data that is included as an element of the Entity Data key. The value of the attribute becomes an element of the key of an instance of the Entity Data type.
Tagged values

AttributeName

The identity of the attribute in the associated Entity Data that is incorporated as an element of the Key.

Constraints

• If the containing Key is designated PrimeKey = true, then the Attribute values that are incorporated into the key must be immutable.

Diagram notation

Attribute

3.11.2.7 Entity

Inheritance

Class
  Process Component
  Data Manager
  Entity

Instantiation in a model

Concrete

Semantics

An Entity is an object representing something in the real world of the application domain. It incorporates Entity Data that represents the state of the real world thing, and it provides the functionality to encapsulate the Entity Data and provide associated business logic.

An Entity instance has identity derived from the Key of its associated Entity Data.

Entity is the abstract super type of all identifiable application domain elements. This includes Entities that have a collection of rules to operate on the state of related entities. It also includes Entities that incorporate process elements that act on other Entities. The rule set and process specializations introduce additional elements, but have the basic characteristics of being identifiable, having local state (Composite Data) often viewed as their “context,” and having relationships to other Entities that they may act upon.

If an Entity is managed, all instances of the type and its sub-types are known, each instance has unique identity, and the type can have operations and attributes associated with the extent (i.e., applicable to all instances). This is typically implemented as a type manager or “home” object that represents the extent.
**Tagged values**

In the list, below, only Managed is introduced as a tagged value by Entity, but NetworkAccess and Sharable, inherited from Data Manager, are also discussed to clarify the implications.

**Probes**

Identifies Data Probe ports associated with the Entity type.

**Managed**

A Boolean value that indicates if the Entity type is managed. If it is managed, then the implementation provides a mechanism for accessing the extent of all instances of the type and its sub-types and may provide a mechanism for dynamically applying rules to all instances. This typically is implemented as a “home” or “type manager.”

**NetworkAccessible**

A Boolean value that indicates if the Entity is expected to be accessed over the network. This implies that it has a network interface (e.g., CORBA IDL). An Entity that is not NetworkAccessible can only be accessed over the network through an associated Entity that is NetworkAccessible.

**Sharable**

A Boolean value that indicates if the Entity can be shared by multiple, concurrent transactions or users. A Sharable Entity will enforce controls to serialize access by concurrent transactions.

An Entity that is not sharable may be instantiated for use by a particular user or transaction. It generally contains a copy of the primary Entity Data instance representing the real world thing. The primary Entity Data instance may be in a database and the copy is created to perform operations on the Entity Data. Alternatively, the Entity Data may be managed by an Entity that is sharable, but the copy is created so that processing can be localized on another server. In either case, it would be expected that the primary Entity Data would be locked when the copy is taken and released when the copy is deleted. Changes to the copy would likely be applied to the primary instance prior to removing the lock.

Entities that are not sharable may also be implemented as value objects, which are always passed by value over the network. While they may have unique identity by association with an identifiable Entity, they may not have a key that reflects this unique identity and their Entity Data does not carry its unique identity when passed by value.

An Entity that is sharable is expected to be persistent. An Entity that is not sharable may be persistent if it is incorporated in the state of a sharable Entity.

**Constraints**

- An Entity manages Entity Data, which may have a key and relationships.
- A managed Entity must have a Primary Key.
- A network Accessible Entity must have a Primary Key
• An Entity that isSharable will serialize concurrent transactions that attempt to access its data.

**Diagram notation**
Equivalent to Class

### 3.11.2.8 Entity Role

**Inheritance**

Class

Process Component  
Data Manager  
Entity  
Entity Role

**Instantiation in a model**

Concrete

**Semantics**

An Entity Role extends its parent Entity for participation in a particular context. An Entity may have a number of associated Entity Roles reflecting participation in multiple contexts. The Entity might have several Entity Roles of the same type at the same time, but each should be associated with a different context.

The context of an Entity Role is also represented by an Entity. The context could be a corporation where the parent is a person and the Entity Role is an employee. A context may have many entity roles of the same type or different types representing participation of different parent Entities for different purposes.

**Tagged values**

*VirtualEntity*

A Boolean value that indicates if the Entity Role incorporates and extends the primary interface of the parent Entity it represents, i.e., it can be used in place of the primary Entity.

**Constraints**

The parent entity of an entity role cannot be dynamically changed.

**Diagram notation**

Equivalent to Class
3.11.2.9 Data Probe

Inheritance

Class
Proto Port
Port
MultiPort
Data Probe

Instantiation in a model

Concrete

Semantics

A Data Probe port is associated with an Entity and accepts ad hoc requests to detect changes in the internal state of the Entity. The Data Probe then forwards messages or events when the states of interest become true until the request is removed. A Data Probe may serve many requests concurrently, producing various message types when the appropriate states occur.

Tagged values

ExtentProbe

ExtentProbe = true indicates that requests apply to the extent of the associated entity as opposed to a particular instance. In implementation, an ExtentProbe would be associated with a “home” or “type manager.”

Constraints

• DataProbes only emit messages (i.e., output only).
• DataProbe can only attach to an Entity with Managed = true.

Diagram notation

Same as Port (from CCA).

Section IV - The Events Profile

The Events profile describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model event driven systems.
3.12 Rationale

3.12.1 Introduction

Event driven computing is becoming the preferred distributed computing paradigm in many enterprises and in many collaborations between enterprises.

Event driven computing combines two kinds of loosely coupled architectures:

- Event driven process architecture. This is a loosely coupled process architecture where the activities are not sequenced in traditional workflow fashion. Rather each participant in the process has autonomous responsibilities and performs those responsibilities on the basis of loosely coupled notifications, (in the supply chain world a.k.a. business signals).

- Publish and subscribe information distribution architecture. Publish and Subscribe is a loosely coupled mechanism for getting information from publishers to subscribers, while keeping the two independent of each other. Publish and subscribe is often implemented as loosely coupled, distributed components that communicate with each other through asynchronous messaging.

In event driven computing the most important aspect of the business process is the events that happen during its execution, and the most important part of the component-to-component communication is the notification of such events from the component that made them happen to all the components that need to react to them.

In ECA we support both the definition of loosely coupled event-driven business processes, and the loosely coupled publish and subscribe communication between distributed components.

Neither the business world, nor the computing world, however, applies only one paradigm to their problem space. Businesses use a combination of loosely coupled and tightly coupled business processes and computing solutions deploy a combination of loosely coupled and tightly coupled styles of communication and interaction between distributed components.

This document describes in detail the event-driven flavor of loosely coupled business and systems models, and also illustrates how such models can co-habit with more tightly coupled models.

An ECA based business process can be defined as event driven for some of its steps and workflow or request/response driven for others. Likewise, distributed components in the ECA component profile can be configured to communicate with each other in a mixture of publish-and-subscribe, asynchronous Point-to-Point, and client-server remote invocation styles.

This document will focus on the purely event driven paradigm.

We will cover the following topics:

- Design Rationale
- Event driven business model
3.12.2 Overall design rationale

This profile is based on the following design principles:

- Alignment with the BOI roadmap (BOM/98-12-04) with respect to business process, business entity, business event, and business rule.
- The event as a central rather than peripheral concept.
- Business Processes should be loosely coupled:
  - Autonomy of participants in a business process
  - Distinction between process and entity
  - Clear separation of business logic, i.e. rules from business execution, i.e. the action taken once rules have been resolved.
- Information distribution should be loosely coupled
  - Use of Publish and Subscribe rather than point-to-point
  - Ubiquitous event notification
  - Asynchronous computing
  - Shared information model
- Loose coupling of the Events profile with the Business Process profile, Entities profile, and component profile
- Re-usability of paradigm
  - Recursive use of event notifications
- Applicability under multiple paradigms
  - The Events profile is intended to support both business process modeling and EAI.
  - The proposed profile is intended for either tightly coupled client/server or peer-to-peer computing, or loosely coupled event-driven computing, or combinations of both.
3.12.3 Concepts

3.12.3.1 Event Based Business Model

An event based business model is driven by business events. Whenever a business event happens anywhere in the enterprise, some person or thing, somewhere, reacts to it by taking some action. Business rules determine what event leads to what action. Usually the action is a business activity that changes the state of one or more business entities. Every state change to an Entity constitutes a new business event, to which, in turn, some other person or thing, somewhere else, reacts by taking some action.

The main concepts in event driven business models are the business entity, business event, business process, business activity and business rule.

This continuous, cyclical view of the interaction between these five business concepts can be depicted as follows:

![Event Based Business Modeling](image)

3.12.3.2 Event Driven Computing

Event driven computing is a computing paradigm where interaction among components is based on notification of what happened, as opposed to instructions of what should happen.

“What happened” is reflected as events. The communication that the event happened is reflected as notifications. The reaction to the notification (or indirectly to the event) is reflected as activities.
Two important layers provide loose coupling between event, notification and activity. The events are decoupled from the act of notification by configurable subscriptions. The act of notification is decoupled from the activity by configurable notification rules. Event driven computing is a very flexible, yet powerful architecture for enterprise distributed object computing. The main architectural principle is that individual components are kept as autonomous as possible, and that the loose coupling and configurability enable rapid reconfiguration of the system to meet changing business model requirements such as mergers, outsourcing and business re-engineering. Under event driven enterprise computing all business entities are self-contained, and typically do not directly change each other’s state.

3.12.3.3 Event Driven Business Computing

Event driven business computing is a paradigm that executes business processes by capturing events that happen in the enterprise, notifying the appropriate other parties in the enterprise or outside the enterprise, and reacting to such notifications. Business processes are configured with a set of subscriptions, and a set of notification rules that determine what activity to start (or end) based on each notification. Business Entities are the people, products, and other business resources and artifacts that business activities operate on. When actions are performed on Business Entities, Business Events happen. All Business Entities are capable of notifying the world of events that happen to them. Business Processes that are capable of subscribing to such event notifications are called EventBasedProcesses. They assign notifications to activities based on a set of Notification Rules.

3.12.3.4 Publish and Subscribe

In a Publish and Subscribe information distribution model, publishers publish information, and subscribers subscribe to information. Publishing simply means make the information openly available for consumption. Subscribing simply means expressing an interest in the information and consuming it when it gets delivered. The information is transferred from Publisher to Subscriber ‘automatically’, usually through the use of asynchronous message middleware. Publishers do not know which subscribers will receiver their data, and subscribers do not know where the information comes from. The information, however, describes the state of a process or an entity that is of interest to both publisher and subscriber, and both parties share the information model that describes these states (and state changes).

3.12.4 Key Concepts of event driven business and system models

3.12.4.1 EventBasedProcess

This is a concept introduced by this ECA Events profile, but based on the Choreography element in the ECA component profile.
EventBasedProcesses are identifiable series of activities that change states of business entities, thereby causing business events. For example, the activities in the Shipping process may cause allocation events against the Inventory Entity, and pick, pack, and ship events against the Shipment Entity.

### 3.12.4.2 Entity
This is a concept from the Entities profile.

Business Entities are representations of entities of significance to the business, identifiable by an ID, operated on during business process execution, and characterized by having a lifecycle expressed as a set of entity states. Examples are Customer, Purchase Order, Product, and Payment. In the Events profile, we use the supertype of Entity, DataManager, as the managers of the data behind an Entity. An EventBasedDataManager is capable of publishing information about all changes to the data it manages. Because a EventBasedDataManager is a kind of EventBasedProcess, it can also publish information about state changes in its internal process.

### 3.12.4.3 BusinessEvent
This is a concept introduced by this ECA Events profile.

BusinessEvents are state changes whose occurrence is of significance to the execution of business processes. Typically business events reflect state changes in Business Entities. These can be thought of as entity events. Examples are the approval of a Purchase Order, or Receipt of a Payment. A more indirect type of business event is a state change to a business process or to a collaboration between two business processes. These are called ProcessEvents.

### 3.12.4.4 Notification
This is a concept introduced by this ECA Events profile. This is a concept only, it is not represented by a specific element in the Events profile. It is implemented using the dataflow part of the Business Process profile.

A notification is a triggered dataflow between two roles, or between two components. The trigger that causes the notification can be 'manual', or timed, or it can be due to the fact that an event has happened. When triggered by an event, it is called an event notification. Event notification, too, is just a concept, and not modeled explicitly.

The notification is always one-way only. The source of the notification is usually an Entity, but can also be an EventBasedProcess. The destination is usually an EventBasedProcess.

A notification can be thought of as the delivery of a set of data from a publisher to a subscriber. The data delivered is a PubSubNotice. A PubSubNotice is just a set of data, it is immutable, and it does not have any behavior of its own. There is no implication in the PubSubNotice as to what the recipient is going to do when it receives the PubSubNotice. An EventNotice is a special kind of PubSubNotice.
All business events are associated with an EventNotice and the corresponding notification will be take place whenever the business event happens successfully.

Similarly, when a business event is supposed to have happened but didn’t, ‘failure’ notifications will be take place.

An EventNotice always conveys the following information:

- the EventBasedProcess or entity the event happened against,
- the trigger that caused it,
- the identification of the before state,
- the after state,
- the change between the two states.

3.12.4.5 Publisher

This is a concept introduced by this ECA events profile.

A publisher is a component that provides PubSubNotices.

3.12.4.6 Subscriber

This is concept introduced by this ECA Events profile.

A subscriber is a role or component that holds subscriptions to one or more PubSubNotices.

3.12.4.7 Subscription

This is a concept introduced by this ECA Events profile.

A subscription establishes a flow of PubSubNotices to the subscriber. A subscription identifies the type of EventNotice, e.g. the kind of event you want to be notified about. A subscription may additionally have a SubscriptionClause associated. The SubscriptionClause functions as a filter much like a where-clause on the content of the notification.

3.12.4.8 NotificationRule

This is a concept introduced by this ECA Events profile.

NotificationRules are rules that govern the execution of (part of) an EventBasedProcess. A NotificationRule is a mapping from a BusinessNotification to an activity, optionally guarded by a EventCondition. An EventCondition is a dependency on the receipt of additional, related PubSubNotices.
3.12.5 Event and Notification based Interaction Models

So the basic building blocks are the EventBasedProcess and the Entity, as shown in Figure 3-37. The two are ‘wired together’ by a flow of actions from process to entity, and by a flow of EventNotices from entity to process. In a component framework, therefore, EventBasedProcesses have EventNotices inflow and action outflow, and Entities have action inflow and EventNotice outflow. A messaging infrastructure manages the delivery of EventNotices from entities to processes. The actions too, incidentally, can be implemented via a messaging infrastructure, but the corresponding messages are usually point-to-point.

This means that we can create CCA EventBasedProcess components and CCA event-based Entity components if we can model:

- A EventBasedProcess as a set of Notification Rules of the type notification/condition/activity (This is the event-driven equivalent of the commonly known even/condition/action rule).
- An event-based Entity as set of action/state/event causalities.

The connection from EventBasedProcess to Entity is governed by a configurable mapping of notification to action, namely the notification rule.

The connection from Entity to EventBasedProcess is governed by a configurable set of subscriptions.

With these building blocks we can model a number of event-based interactions. And by reconfiguring the Notification Rules and/or the Subscriptions, we can easily re-engineer the business process and its execution in the system.

The very simplest model is a single process affecting a single entity, but this is not very interesting.

The simplest model of interest is a single process affecting multiple entities.

A slightly more complex interaction is process-to-process notifications. This model is used in supply chain models, a.k.a. business signal.

Another flavor of interaction is the delegation of the responsibility to deal with notifications. This model is used in EAI integration where legacy applications can be “wrapped” behind publishers and subscribers of notifications.

These three flavors map to three kinds of interaction in the component model: Interaction between a master and slave component, interaction between two peer components, and interaction between the boundary of a component and its subcomponents.

Yet another kind of interaction that can also be based on events and notifications is a collaboration between processes. This model is used often in b2b interactions. Even web services can be implemented using event concepts and loosely coupled messaging.
3.12.5.1 Intra Process Event Notification

The simplest model a single process affecting multiple entities. This can be modeled pictorially something like this:

![Intra Process Event Notification Diagram](image)

*Figure 3-37 Intra Process Event Notification*

This corresponds to interaction between a master and a set of slave components. The process has the logic to evaluate notifications and invokes actions on the entities.

3.12.5.2 Cross Process Event Notification

A picture of loosely coupled cross process notification:
Figure 3-38  Cross Process Event Notification

This corresponds to interaction between two peer components.

3.12.5.3 Delegation

Delegation is passing on of a responsibility. Relative to the event driven model, delegation is the passing of the business notification to another process, for it to resolve, typically a sub process. There is a distinct expectation that the business activity will happen, but it will happen as part of the sub process, not in the main process. However, to the outside processes it will appear as if the main process performed the business activity, and any event will look like they happened in the main process and any notifications will come from the main process.
In the component model this the interaction between the boundary of a component and its subcomponents.

3.12.6 Leveraging event based models

3.12.6.1 Business Event Types

A variety of standard event types enable a rich set of event-based scenarios.

Success events

A success event is the ‘normal’ event. It reflects the successful execution of an action on an entity or the successful initiation or completion of an activity within the process.

Failure events

A failure event is a type of ‘exception’ event. It reflects that an action on an entity was attempted but failed, or that the initiation of an activity failed, or that an activity was forced to terminate unsuccessfully. In programming languages this is the equivalent of ‘raising an exception.’
**TimeOut-Events**

This is one of the most useful events for management. A TimeOut-event is an abstract event that reflects that something should have happened within a certain time period, but didn’t. Typically this would be something like ‘shipment was scheduled but did not happen’ within the allotted time. This can be generated based on an overdue condition relative to a scheduled time.

**Mutual exclusion events**

This type of event signifies that a given event that might be expected according to the business process, did not happen, due to another alternative event happening. This may be due to the process calling for a mutually exclusive choice between two parallel events, or based on the occurrence of an event that normally happens after the event in question, indicating that an event was ‘skipped.’

**Data change events**

These are useful for replication of data from one place to another. Whenever the source data changes, events are generated, even if the change in data is not considered an event in an entity life cycle sense.

**Timed notifications**

This is in some sense the simplest kind of notification; it is simply an alarm clock or planning calendar. You can schedule notifications based on a schedule of trigger times. The event, in some sense, is the clock reaching the scheduled time. The notification is usually about the state of something as per that time, or in some cases it could be the timed release of a number of accumulated event notifications.

**3.12.6.2 Event Algebra**

Events may be ANDed/ ORed, included, excluded, to create new event types.

For instance creditApproved event, and shipmentReady event may be ANDed to releaseApproved event.

For instance orderApproved event and NOT licenseDenied event may be ANDed to shipmentReleased event.

For instance orderShipped event, and NOT shipmentInvoiced event may be ANDed to invoice exception event.

For instance orderShipped event and orderCanceled event may be ORed to produce an orderClosed event.

Such event algebra is performed by value-added event agents. They take event notifications as their input and produce value added event notifications as their output.

Such an agent could also be turning event notifications into time-released notifications.
3.12.6.3 Management by Exception

One of the most important ways to leverage event driven computing is to manage by exception notifications. If the business model defines all the events that should occur in the normal course of business, then intelligent agents can be set up to track the progress of each process instance and issue notifications whenever something happened too late or didn’t happen at all. These agents would issue timeout-event notifications, mutual exclusion event notifications, and other exception notifications.

Event notifications can also be used to monitor workloads and to give input for rebalancing of loads within a process.

3.13 Metamodel

This is a meta-model for event-driven business computing, specifying the concepts described above. The model consists of two packages:

- Publish and Subscribe Package
- Event Package

These two packages are described in detail below, but first we show two views across the packages:

- Process View (showing how a Business Process produces and reacts to events)
- Entity View (showing how Business Entities produce and react to events)

We also show both packages and both views together in a full overview diagram of the metamodel for the Events profile.

3.13.1 Business Process View

This is an overview of the business process aspect of event-driven business computing. The yellow (shaded) elements are directly part of the business process view. The white elements belong to other views and provide the context for this view (see Figure 3-40).
An EventBasedProcess is a specialized choreography. A choreography (from the CCA Profile) is a set of Nodes (States and PortUsages) and the Connections between them. An EventBasedProcess generates ProcessEvents upon successful or failed entry into or exit from its Nodes. A ProcessEvent is a kind of BusinessEvent. An EventBasedProcess is a Publisher and will publish EventNotices for each of its ProcessEvents. An EventBasedProcess is also a Subscriber and will hold subscriptions to PubSubNotices, specifically EventNotices from other processes and from entities.

The NotificationRule is the loose coupling between the receipt of a EventNotice and entry into or exit from a Node. One or more EventConditions may guard the NotificationRule. An EventCondition requires the receipt of an additional EventNotice, governed by another subscription.
3.13.2 Entity View

This is an overview of the entity aspect of event-driven business computing. The yellow (shaded) elements are directly part of the entity view. The white elements belong to other views and provide the context for this view.

![Entity View of Event Model](image)

In the Entities profile Entity is a kind of DataManager. Further, a DataManager is a kind of Choreography. An EventBasedDataManager is a special DataManager that generates DataEvents each time its data changes. DataEvents are a kind of BusinessEvent. Since a DataManager is also a kind of Choreography, it can also generate ProcessEvents about its own internal choreography.

3.13.3 Whole Event Model

The following is a diagram of the whole metamodel for the Events profile. The yellow (shaded) elements are directly part of the metamodel, and will be described in detail below, divided into two packages: Publish and Subscribe, and Event. The white elements belong to other profiles and provide the context for this view.
Figure 3-42 Complete Metamodel for Event Modeling
3.13.4 Publish and Subscribe Package

This is an overview of the publish and subscribe aspect of event-driven business computing. The yellow (shaded) elements are directly part of the publish and subscribe package. Each of them will be described in detail below. The white elements belong to other views and provide the context for this view.

Publish and Subscribe (PubSub) Package

A publisher is a component that offers a list of publications, and produces (publishes) PubSubNotices accordingly. Publication is the commitment to send PubSubNotice. PubSubNotice is the data structure in which the PubSubNotice instances will be published.

EventNotice is a kind of PubSubNotice.

A subscriber is a component that holds Subscriptions, and receives PubSubNotices accordingly. Subscription is the loose coupling between the sending of the notice and the receipt of the notice. A subscriptionClause determines whether the subscriber gets notified or not.

Figure 3-43  Metamodel of event notification view
Notification is the sending of an PubSubNotice from the Publisher to the Subscriber when an event happens within the Publisher. This is usually handled by middleware, and publisher and subscriber are loosely coupled and anonymous relative to each other.

3.13.4.1 Publisher

**Semantics**
A publisher is a component that exposes a list of publications, and produces PubSubNotices accordingly.

**UML base element(s) in the Profile**
Class

**Fully Scoped name**
EDOC::CCA::Event:: Publisher

**Owned By**
None

**Properties**
None

**Related elements**
Publication
Publisher offers one or more Publications

**Constraints**
None

3.13.4.2 Publication

**Semantics**
A Publication is a declaration of capability and intent to produce a PubSubNotice.

**UML base element(s) in the Profile**
Inherits from FlowPort in CCA Profile

**Fully Scoped Name**
EDOC::CCA::Event:: Publication
 Owned By
Publisher

Properties

publicationClause
Expression based on attributes of PubSubNotice, describing the instance subset that will be produced according to this publication.

domain
A domain in which the PubSubNotices for this publication will be produced.

Related Elements

Publisher
A Publication is offeredBy exactly one Publisher.

PubSubNotice
A Publication announces one or more PubSubNotices.

FlowPort
A Publication Inherit from FlowPort as per the Component Profile.

Constraints
PublicationClause Expression is constrained to the values of the attributes of the associated EventNotice.

3.13.4.3 Subscriber

Semantics
A subscriber is a role or component that exposes a list of subscriptions, and consumes PubSubNotices accordingly.

UML base element(s) in the Profile
Class

Fully Scoped Name
EDOC::CCA::Event:: Subscriber

Owned By
None
Properties
None

Related elements
Subscription
A Subscriber holds one or more Subscriptions.

Constraints
None

3.13.4.4 Subscription

Semantics
Subscription is the expression of interest in receiving and capability to receive a PubSubNotice.

UML base element(s) in the Profile
Inherits from FlowPort in Component Profile.

Fully Scoped Name
EDOC::CCA::Event:: Subscription

Owned By
Subscriber

Properties
subscriptionClause
Expression based on attributes of PubSubNotice, describing the instance subset of interest to this subscription.

domain
A domain of interest. Only PubSubNotices produced within this domain are of interest.

Related Elements
Subscriber
A Subscription is heldBy exactly one Subscriber.

EventNotice
A Subscription subscribesTo one or more EventNotices.
FlowPort
A Subscription Inherits from FlowPort as per Component Profile.

Constraints
SubscriptionClause Expression is constrained to the values of the attributes of the associated EventNotice. If the subscription is for more than one event notice, the expression is constrained to attributes that are common to all the event notices of interest.

3.13.4.5 PubSubNotice

Semantics
A PubSubNotice is any data structure that is announcedBy a publication and/or subscribedTo by a subscription. Instances of PubSubNotice are communicated as DataFlows from publishers to subscribers based on the subscriptions.

UML base element(s) in the Profile
Inherits from CompositeData as per Entities profile.

Fully Scoped Name
EDOC::CCA::Event:: PubSubNotice

Owned By
None

Properties
None

Related Elements
Subscription
A PubSubNotice is subscribedBy one or more Subscriptions.

Publication
A PubSubNotice announcedBy one or more Publications.

CompositeData
A PubSubNotice Inherits from CompositeData as per Entities profile.

Constraints
None
3.13.5 Event Package

This is an overview of event aspect of event-driven business computing. The yellow (shaded) elements are directly part of the event package. Each of them will be described in detail below. The white elements belong to other views and provide the context for this view.

![Diagram of Event Package](image)

**Figure 3-44** Diagram of Event Package

3.13.5.1 BusinessEvent

Semantics

A business event is any event of business interest that happens within an enterprise. BusinessEvents are either ProcessEvents or DataEvents.

**UML base element(s) in the Profile**

Class
**Fully Scoped Name**
EDOC::CCA::Event:: BusinessEvent

**Owned By**
None

**Properties**
None

**Related Elements**

*EventNotice*
A business event *triggers* one or more event notices.
A business event is *describedBy* one or more event notices.

*ProcessEvent*
Business event is the Abstract supertype of ProcessEvent.

*DataEvent*
Business event is the Abstract supertype of DataEvent.

**Constraints**
None

### 3.13.5.2 ProcessEvent

**Semantics**
A process event is any business event that reflects a state change within a process, i.e. entry into or exit from Nodes in a Choreography.

**UML base element(s) in the Profile**

*Inherits* from BusinessEvent

**Fully Scoped Name**
EDOC::CCA::Event:: ProcessEvent

**Owned By**
EventBasedProcess
Properties
None

Related Elements

Node
A ProcessEvent reflects the entry into or exit from one Node (or the exit from one and entry into another, i.e., two Nodes).

BusinessEvent
ProcessEvent Inherits from BusinessEvent.

Constraints
Any Node referenced must belongs to the EventBasedProcess that also owns this ProcessEvent.

3.13.5.3 DataEvent

Semantics
A data event is any business event that reflects a changes in data managed by a DataManager.

UML base element(s) in the Profile
Inherits from BusinessEvent

Fully Scoped Name
EDOC::CCA::Event:: DataEvent

Owned By
EventBasedDataManager

Properties
None

Related Elements

BusinessEvent
ProcessEvent Inherits from BusinessEvent.

Constraints
None
3.13.5.4 EventNotice

**Semantics**
An event notice is any PubSubNotice that is triggered by a business event.

**UML base element(s) in the Profile**
Inherits from PubSubNotice

**Fully Scoped Name**
EDOC::CCA::Event:: EventNotice

**Owned By**
None

**Properties**
None

**Related Elements**

*BusinessEvent*
An event notice is triggeredBy exactly one Business Event.
An event notice may describe at most one Business Events.

*PubSubNotice*
An event notice Inherits from PubSubNotice.

**Constraints**
None

3.13.5.5 EventBasedProcess

**Semantics**
An EventBasedProcess is a subtype of Choreography (CCA profile). It is a Subscriber and has NotificationRules associated with its Subscriptions. It is a Publisher and publishes ProcessEvents. ProcessEvents describe the life cycle of the EventBasedProcess.

**UML base element(s) in the Profile**
Inherits from Choreography (from CCA profile).
**Fully Scoped Name**
EDOC::CCA::Event:: EventBasedProcess

**Owned By**
None

**Properties**
None

**Related Elements**

*ProcessEvent*
An EventBasedProcess owns a set of ProcessEvents which together describes the life cycle of the EventBasedProcess.

*Choreography*
An EventBasedProcess *Inherits* from Choreography (from CCA profile).

*Publisher*
An EventBasedProcess *Inherits* from Publisher.

*Subscriber*
An EventBasedProcess *Inherits* from Subscriber.

*EventBasedDataManager*
An EventBasedProcess is the supertype of EventBasedDataManager.

**Constraints**
None

### 3.13.5.6 EventBasedDataManager

**Semantics**
An EventBasedDataManager is a DataManager. It is also a Publisher and publishes DataEvents when its data changes. It may also be a subscriber, typically subscribing to PubSubNotices relating to the maintenance of its data, e.g., replication.

**UML base element(s) in the Profile**
*Inherits* from DataManager (from Entities profile).
Fully Scoped Name
EDOC::CCA::Event::EventBasedDataManager

Owned By
None

Properties
None

Related Elements

DataEvent
An EventBasedDataManager owns a set of DataEvents which together describes possible changes to the data owned by the EventBasedDataManager.

DataManager
An EventBasedDataManager Inherits from DataManager (from Entities profile).

Publisher
An EventBasedDataManager Inherits from Publisher.

Subscriber
An EventBasedDataManager Inherits from Subscriber.

EventBasedDataManager
An EventBasedDataManager inherits from EventBasedProcess.

Constraints
None

3.13.5.7 NotificationRule

Semantics
An NotificationRule is a rule associated with a subscription which determines what should happen within the EventBasedProcess holding the subscription when a qualifying PubSubNotice is delivered. Optionally the NotificationRule can be further guarded by an EventCondition that requires the delivery of additional events.
**UML base element(s) in the Profile**

*Class*

**Fully Scoped Name**

EDOC::CCA::Event:: NotificationRule

**Owned By**

EventBasedProcess

**Properties**

*Condition*

An Expression based on attributes of PubSubNotice, describing the instance subset of the PubSubNotice that will cause the change in the EventBasedProcess indicated by this NotificationRule

**Related Elements**

*Subscription*

A NotificationRule is associated with a Subscription and ‘fires’ upon receipt of the PubSubNotice associated with the Subscription.

*EventCondition*

A NotificationRule may be guardedBy one or more EventConditions calling for the receipt of additional events before this NotificationRule will ‘fire’ successfully.

*Node*

A NotificationRule governs the entry into or exit from one Node (or the exit from one and entry into another, i.e., two Nodes).

**Constraints**

Any EventConditions must reference Subscriptions belonging to the same EventBasedProcess as the NotificationRule.

### 3.13.5.8 EventCondition

**Semantics**

An EventCondition identifies a subscription and specifies a PubSubNotice instance subset of which one must have been received to satisfy this condition.
UML base element(s) in the Profile

Class

Fully Scoped Name

EDOC::CCA::Event::EventCondition

Owned By

NotificationRule

Properties

Condition

An Expression based on attributes of PubSubNotice, describing the instance subset of the PubSubNotice that will satisfy the guard constituted by this EventCondition.

Related Elements

Subscription

An EventCondition is requires a Subscription and ‘fires’ upon receipt of a PubSubNotice associated with the Subscription. If the received PubSubNotice satisfies the condition expression, then the EventCondition has been satisfied.

Constraints

None

3.14.2 Introduction

The following lists, divided into two packages, the elements in the Events profile.

3.14.3 Publish and Subscribe Package

3.14.3.1 Publisher

Inheritance
Class
Publisher

Instantiation in a model
Concrete

Semantics
A publisher is a component that exposes a list of publications, and produces PubSubNotices accordingly.

Tagged Values

offers
Reference: Publisher offers one or more Publications.

Constraints
None

3.14.3.2 Publication

Inheritance
Class
ProtoPort
Port
Flowport
Publication

Instantiation in a model
Concrete

Semantics
A Publication is a declaration of capability and intent to produce a PubSubNotice.

Tagged Values

publicationClause
Expression based on attributes of PubSubNotice, describing the instance subset that will be produced according to this publication.

domain
A domain in which the PubSubNotices for this publication will be produced.

Publisher
Reference: A Publication is offeredBy exactly one Publisher.

announces
Reference: A Publication announces one or more PubSubNotices.

Constraints
PublicationClause Expression is constrained to the values of the attributes of the associated EventNotice.

3.14.3.3 Subscriber

Inheritance
Class
Subscriber

Instantiation in a model
Concrete

Semantics
A subscriber is a role or component that exposes a list of subscriptions, and consumes PubSubNotices accordingly.
Tagged Values

holds
Reference: A Subscriber holds one or more Subscriptions.

Constraints
None

3.14.3.4 Subscription

Inheritance
Class
ProtoPort
Port
Flowport
Subscription

Instantiation in a model
Concrete

Semantics
Subscription is the expression of interest in receiving and capability to receive a PubSubNotice.

Tagged Values

subscriptionClause
Expression based on attributes ofPubSubNotice, describing the instance subset of interest to this subscription.

domain
A domain of interest. OnlyPubSubNotices produced within this domain are of interest.

heldBy
Reference: A Subscription is heldBy exactly one Subscriber.

subscribesTo
Reference: A Subscription subscribesTo one or more EventNotices.
Constraints
SubscriptionClause Expression is constrained to the values of the attributes of the associated EventNotice. If the subscription is for more than one event notice, the expression is constrained to attributes that are common to all the event notices of interest.

3.14.3.5 PubSubNotice

Inheritance
Class
CompositeData
PubSubNotice

Instantiation in a model
Concrete

Semantics
A PubSubNotice is any data structure that is announcedBy a publication and/or subscribedTo by a subscription. Instances of PubSubNotice are communicated as dataflows from publishers to subscribers based on the subscriptions.

Tagged Values
subscribedBy
Reference: A PubSubNotice is subscribedBy one or more Subscriptions.

announcedBy
Reference: A PubSubNotice announcedBy one or more Publications.

Constraints
None

3.14.4 Event Package 2

3.14.4.1 BusinessEvent

Inheritance
Class
BusinessEvent
Instantiation in a model

Abstract

Semantics
A business event is any event of business interest that happens within an enterprise. BusinessEvents are either ProcessEvents or DataEvents.

Tagged Values

triggers
Reference: A business event triggers one or more event notices.

describedBy
Reference: A business event is describedBy one or more event notices.

Constraints
None

3.14.4.2 ProcessEvent

Inheritance
Class
BusinessEvent

Instantiation in a model
Concrete

Semantics
A process event is any business event that reflects a state change within a process, i.e. entry into or exit from Nodes in a Choreography.

Tagged Values

reflects
Reference: A ProcessEvent reflects the entry into or exit from one Node (or the exit from one and entry into another, i.e. two Nodes).

Constraints
Any Node referenced must belong to the EventBasedProcess that also owns this ProcessEvent.
3.14.4.3 DataEvent

Inheritance
Class
    BusinessEvent
    DataEvent

Instantiation in a model
Concrete

Semantics
A data event is any business event that reflects a changes in data managed by a DataManager.

Tagged Values
None

Constraints
None

3.14.4.4 EventNotice

Inheritance
Class
    CompositeData
    PubSubNotice
    EventNotice

Instantiation in a model
Concrete

Semantics
An event notice is any PubSubNotice that is triggered by a business event.

Tagged Values
triggeredBy
Reference: An event notice is triggeredBy exactly one Business Event
An event notice may describe at most one Business Events.

**Constraints**
None

### 3.14.4.5 EventBasedProcess

**Inheritance**
- Choreography
  - EventBasedProcess

**Instantiation in a model**
Concrete

**Semantics**
An EventBasedProcess is a subtype of Choreography. It is a Subscriber and has NotificationRules associated with its Subscriptions. It is a Publisher and publishes ProcessEvents. ProcessEvents describe the life cycle of the EventBasedProcess.

**Tagged Values**
None

**Constraints**
None

#### 3.14.4.6 EventBasedDataManager

**Inheritance**
- Choreography
  - ProcessComponent
    - DataManager
      - EventBasedDataManager

**Instantiation in a model**
Concrete
Semantics
An EventBasedDataManager is a DataManager. It is also a Publisher and publishes DataEvents when its data changes. It may also be a subscriber, typically subscribing to PubSubNotices relating to the maintenance of its data, e.g., replication.

Tagged Values
None

Constraints
None

3.14.4.7 NotificationRule

Inheritance
Class
NotificationRule

Instantiation in a model
Concrete

Semantics
A NotificationRule is a rule associated with a subscription which determines what should happen within the EventBasedProcess holding the subscription when a qualifying PubSubNotice is delivered. Optionally the NotificationRule can be further guarded by an EventCondition that requires the delivery of additional events.

Tagged Values

Condition
An Expression based on attributes of PubSubNotice, describing the instance subset of the PubSubNotice that will cause the change in the EventBasedProcess indicated by this NotificationRule.

subscription
Reference: A NotificationRule is associated with a Subscription and ‘fires’ upon receipt of the PubSubNotice associated with the Subscription.

guardedBy
Reference: A NotificationRule may be guardedBy one or more EventConditions calling for the receipt of additional events before this NotificationRule will ‘fire’ successfully.
Node
A NotificationRule governs the entry into or exit from one Node (or the exit from one and entry into another, i.e., two Nodes).

Constraints
Any EventConditions must reference Subscriptions belonging to the same EventBasedProcess as the NotificationRule.

3.14.4.8 EventCondition

Inheritance
Class
EventCondition

Instantiation in a model
Concrete

Semantics
An EventCondition identifies a subscription and specifies a PubSubNotice instance subset of which one must have been received to satisfy this condition.

Tagged Values
Condition
An Expression based on attributes of PubSubNotice, describing the instance subset of the PubSubNotice that will satisfy the guard constituted by this EventCondition.

requires
Reference: An EventCondition is requires a Subscription and ‘fires’ upon receipt of a PubSubNotice associated with the Subscription. If the received PubSubNotice satisfies the condition expression, then the EventCondition has been satisfied.

Constraints
None

3.15 Relationship to other ECA profiles

3.15.1 Relationship to Business Process profile and Entities profile

The ECA Business Process profile describes a process as a set of activities.
Activities are defined in terms of responsible party, performers, artifacts, and pre and post conditions.

Activity diagrams may be used to show roles and flow between activities.

Collaboration diagrams may be used to show roles and message flow between roles.

The Business Process profile does not specify which performers act on what artifacts, and how.

It does not specify directly the relationship between states of artifacts and the pre and post conditions of activities.

It does not show directly what triggers each activity.

(Above three statements are qualified: other than as annotated in activity diagram as control flow and object flow.)

The Business Process profile, relies on components to implement the choreography. The states and transitions of choreography implement the control flows of the activity diagram.

The messages implement the information flows from the collaboration diagram.

The Events profile (this profile) describes events that happen to artifacts (entities). It describes business events as changes from one state to another. The Events profile describes how activities result in state changes, i.e. events.

It describes how these BusinessEvents map to EventNotices, and how subscriptions can channel notifications to processes, and how delivery of a EventNotice can be mapped by NotificationRules to activities.

The Events profile does not describe who or what within the process establishes the subscription, or who or what within the process reacts to receipts of notifications.

### 3.15.2 Relationship to ECA CCA profile

#### 3.15.2.1 Modeling Events with Components

Events are changes in state to either entities or processes.

Just about anything that happens in a business, has interest to someone else, and so every event (to an entity or to a process) has the potential for causing notification.

At the system level this means that any process or entity has to offer notification (i.e. allow subscription) to any of its state change notifications.

Most event notifications also trigger rules of some kind. If state of inventory changes to ‘below-minimum-stock-level’ some re-order rule kicks in. If state of the order-process changes to ‘over-due’ then some expediting rule kicks in.

At the system level this means that NotificationRules and BusinessConditions must be able to refer to events.

All activities result in a new state, or in failure.
At the system level this means that definitions of activities and operations include postconditions. These postconditions could be either expressions of events (i.e. state change), or more likely expression of state (where the state change, or event, is implicit.).

The Events profile relies on the CCA profile to implement the outgoing event notification flows from an entity component, and the incoming event notification flows to a process component. Event notification flows happen from flow port to flow port.

The Events profile relies on the CCA profile to implement the linkage between (the completion of) an action on an entity and (an instance of) an event. The event model specifies which activity causes which event.

### 3.16 Relationship other paradigms

In general the central idea of event driven computing is that event notifications trigger action and/or communication, and that very little action or communication is not triggered by event notifications.

There are four main kinds of communication:

- **Business notification**: A one-way, information-only, notification. A special subtype is event-notification that informs that an event just happened. This is the main form of communication in event-driven computing.

- **Query**: A two-way, request, response, with the response being the query result set. This is a more tightly coupled model. However a query could be triggered by the loosely coupled receipt of a business notification. Also the gathering of data for a business notification could require one or more tightly coupled queries.

- **Collaboration**: A two-way, negotiation-style, communication that may or may not result in a new state between the parties. An atomic style subtype is the ebXML business transaction. This could be implemented in many ways. One way is to consider the requests and responses in the collaboration to simply be business notifications. Regardless how the collaboration itself is implemented, it could certainly be triggered by the loosely coupled receipt of a business notification. For instance notification of an event within the enterprise might trigger the collaboration to order more inventory.

- **Method invocation**: A one-way, with optional return parameters, communication that usually causes the state at the remote end to change in a predefined way. Again, a method invocation could be triggered by the loosely coupled receipt of a business notification. Also under event driven computing entity operations, which are often implemented as method invocations, will trigger the sending of one or more loosely coupled event notifications. A cousin of method invocation, web service invocation, is usually likely to be implemented as one way transfer of messages over standard internet protocols. As such you could easily have web services react directly to event notifications.

So again, event notifications can trigger many kinds of communication, and based on business rules and or subscriptions, the kind of communication may be another notification, a collaboration, a method invocation or a query.
Many times a tightly coupled systems model can be replaced with an event based model to create more flexibility in business and systems re-engineering. Generically, replacing state machines with event-driven computing always adds loose coupling. In a state machine, the event is both the thing that happened and the stimulus for something else to happen. The two cannot be separated. In event driven computing the event, the sending of a notification, the receipt of the notification, and the reaction to the notification are all separate, and can be much more easily reconfigured upon demand. The above is true both at a generic business level and at a system level.

3.16.1 ebXML

ebXML is a large initiative to model and implement business collaborations based on XML message exchanges between the parties.

There are several relationships of the event model to ebXML.

First, event driven computing within the enterprise is the best way to determine when to initiate business collaborations.

Second, the XML message exchanges could themselves be treated as business notifications.

Thirdly, the ebXML business model is based in part on a model for exchange of economic resources, where each such exchange is called an economic event. The capture of such economic events is similar to the capture of normal business events, and the communication of the notifications can be the same for both.

Fourth, the model for economic resources deals also with future commitments, which can be thought of as promises to execute economic events in the future. This extends the event model into prediction of events and executions against those predictions.

ebXML, phase one, was approved in May of 2001. In this phase, the ebXML business process choreography is already near identical to the ECA choreography. It is predicted that ebXML phase two will bring further alignment to ECA, and to the evolving web services standards.

3.17 Example

In the engineering of EventBasedProcesses you identify the business entities to be affected and examine their available business events and ‘communicated’ business notifications. Activities for the EventBasedProcess are then constructed to contain NotificationRules that ‘listen’ for the appropriate business notifications, and business activities that cause the appropriate business events to happen. The process can easily be re-engineered by changing the subscriptions, or the NotificationRules, thus causing different business activities to happen in response to a given business notification.

A basic EventBasedProcess, and its relationships to business entities can be depicted on a diagram such as that below
Processes and entities are depicted as large boxes. Activities within a process are ovals. Events are ‘dog-eared’ boxes. Entity operations are fat arrows. Entity states are hexagons. Business notifications are arrows from event boxes to the left side of process boxes. Invocations of entity operations are arrows from activity ovals to the fat arrows.

This diagram contains notational elements that can (almost) all be mapped directly to an Activity Diagram for the EventBasedProcess, a State Chart for the Entity, and a Sequence Diagram for the interaction between the two.

**Section V - The Business Process Profile**

The Business Process profile specializes the CCA, and describes a set of UML extensions that may be used on their own, or in combination with the other EDOC elements, to model system behavior in the context of the business it supports.
3.18 Introduction

The Business Process profile provides modeling concepts that allow the description of business processes in terms of a composition of business activities, selection criteria for the entities that carry out these activities, and their communication and coordination. In particular, the Business Process profile provides the ability to express:

- Complex dependencies between individual business tasks (i.e., logical units of work) constituting a business process, as well as rich concurrency semantics.
- Representation of several business tasks at one level of abstraction as a single business task at a higher level of abstraction and precisely defining relationships between such tasks, covering activation and termination semantics for these tasks.
- Representation of iteration in business tasks.
- Various time expressions, such as duration of a task and support for expression of deadlines.
- Support for the detection of unexpected occurrences while performing business tasks that need to be acted upon, i.e., exceptional situations.
- Associations between the specifications of business tasks and business roles that perform these tasks and also those roles that are needed for task execution.
- Initiation of specific tasks in response to the occurrence of business events.
- The exposure of actions that take place during a business process as business events.

3.19 Metamodel

This model is organized with three main model elements to describe a business process: `BusinessProcess`, `CompoundTask` and `Activity` as shown in Figure 3-46 in which the derivation from the CCA is shown. BusinessProcess is the outermost layer of composition representing a complete process specification. It is a ProcessComponent for the purpose of its usage inside other CCA Compositions, but its Composition is constrained in the same way as a CompoundTask. In other words, BusinessProcesses are the entry point from CCA to a process definition. CompoundTasks are also specializations of CCA ProcessComponents, but their Ports are constrained specializations of CCA Ports which represent the data required to initiate an enactment of its Composition, which defines how it executes. The only ComponentUsages CompoundTasks and BusinessProcesses may contain are Activities, which are specializations of CCA ComponentUsages. Activities are the pieces of work required to complete a Process, and CompoundTasks are the containers for a logical set of Activities and the `DataFlows` that define the temporal and data dependencies between them. DataFlows are specializations of CCA Flows that connect the PortConnectors on the Activities. Activities are always usages of a CompoundTask definition, which defines the Port types and their correlation semantics. CompoundTasks defining an Activity either compose additional Activities and DataFlows to show how this Activity is performed, or the Activity also refers to a `Performer ProcessRole` via the `performedBy` association, which is a binding to a ProcessComponent that fulfils the requirements of the `ProcessRole`. Performer ProcessRoles are the exit point from a process definition which allows it to invoke ProcessComponents (and their
specializations, such as Entities). Many Activities may be usages of the same CompoundTask definition, and many activities in the same CompoundTask may be performed by the same ProcessRole.

(See Section 3.23 for the combined Process Model)

![Diagram](image)

**Figure 3-46** Composition of Process ModelElements.

DataFlows (constrained Flows) allow the connection of the ProcessPortConnectors representing the ProcessFlowPorts of a CompoundTask to the ProcessPortConnectors of its contained Activities and vice versa. We will call the ProcessPortConnectors representing usage of a ProcessFlowPort in an InputGroup **input ProcessPortConnectors**. Likewise the ProcessPortConnectors representing usage of a ProcessFlowPort in an OutputGroup or ExceptionGroup are called **output and exception ProcessPortConnectors**, respectively.

The flow of data typically goes from input ProcessPortConnectors of the CompoundTask to the input ProcessPortConnectors of an Activity contained by the CompoundTask, and then from the output ProcessPortConnectors of the Activity to either the input ProcessPortConnectors of another contained Activity or to the output or exception ProcessPortConnectors of the CompoundTask.

ProcessFlowPorts are the formal types of inputs to and outputs from a CompoundTask. They have a multiplicity, given by the attribute pair `multiplicity_lb` and `multiplicity_ub`, which indicates the lower bound on the number of values that needs to be received or transmitted by the PortConnector instantiating this port type at runtime, as well as the upper bound on the number of values that the PortConnector can hold before it begins discarding them.
Multiports are used to aggregate FlowPorts. The MultiPort specializations, InputGroup, OutputGroup and ExceptionGroup, indicate that a set of ProcessFlowPorts, when used in some Composition, must all receive values from DataFlows before any of the values are received or transmitted by the CompoundTask which owns them. The can be considered to be correlators. A ProcessMultiPort may be synchronous or asynchronous, as indicated by its synchronous attribute inherited from Port. Usages of Synchronous ProcessMultiPorts indicate the initiation or termination of the execution of some Activity owning the PortUsage, whereas usages of asynchronous ProcessMultiPorts may only have the values in their contained ProcessFlowPorts transmitted into or out of an already executing Activity.

Figure 3-47  Inputs and Outputs of Process ModelElements.

In addition:

• An Activity may specify required Artifact(s) that select information entities to be used or produced.
• An Activity may specify ResponsibleParty(s) that select people, company, or other group roles that are responsible for the Activity.

• Each Activity may have ActivityPreCondition(s) and ActivityPostCondition(s) that further constrain when it starts and how it completes (see Process Model Patterns, Section 3.22).

Figure 3-48 Diagram of the Roles aspect of the Process Model.

The model in Figure 3-48 shows the ownership of ProcessRoles by CompoundTasks (via their ProcessComponent base class). ProcessRoles have three kinds of relationships with Activities. An Activity may be performedBy a ProcessRole, or it is possible that an Activity has a usesArtifact association with a ProcessRole, or a ProcessRole may be responsible for an Activity, as indicated by a responsibleFor association end role. The same ProcessRole may have several associations with different Activities, for example to be the performer for one activity, while also being an artifact for another, or to be both the responsible party and performer for an Activity. The specific ProcessRoles of Performer, Artifact and ResponsibleParty are constrained to be associated with Activities only by the performedBy, usesArtifact and responsibleFor associations respectively, and are useful in many cases where ProcessRoles do not need to be re-used.
At run time a ProcessRole represents the binding of a state variable in its owner CompoundTask to a concrete ProcessComponent instance that meets the requirements of the **selectionRule** or **creationRule** attributes of the ProcessRole. Typically the performer roles of an Activity will have a type from which the defining CompoundTask of that Activity have been derived. The OperationPorts of the ProcessComponent identified by the ProcessRole will be represented as a pair of an InputGroup and an OutputGroup that contain ProcessFlowPorts that represent the input and output parameters of the OperationPort. Exceptions are represented by additional ExceptionGroups.

In addition to the basic set of model elements given above, there are a number of other important concepts required in the modeling of Processes that can be expressed as patterns of use of these basic elements:

- ActivityPreCondition
- ActivityPostCondition
- Timeout
- Terminate
- Loops
  - Simple Loop
  - While and Repeat/Until Loop
  - For Loop
- Multitask

These are explained in Section 3.22, “Process Model Patterns,” on page 3-270. An example of a CompoundTask containing Activities is shown in Figure 3-49.
3.19.1 Business Process metamodel

The metamodel for the Business Process profile is contained in a single package, BusinessProcess.

3.19.1.1 CompoundTask

Semantics

A CompoundTask defines how to coordinate a set of related Activities that, in combination, perform some larger scale activity, ultimately in the context of a Business Process. It represents the formal type and Correlation Protocol Contract of Ports available on Activities that use the CompoundTask. It is also a container (Composition) of Activities that use other CompoundTasks (or, when describing recursion, that re-use this CompoundTask), a container of the DataFlows between these Activities, and the ProcessRoles which model bindings to Objects required by these Activities.
**UML base element(s) in the Profile and Stereotype**

**Associated elements**

**Constraints**

**3.19.1.2 Activity**

**Semantics**

Activity represents the execution of a part of a Business Process using one of two mechanisms (but not both). The mechanisms are:

- The creation of a Composition of nested Activities, ProcessRoles and DataFlows described by the CompoundTask that the Activity references through its uses association.
- The execution of some feature of an Object bound to a ProcessRole instance referred to via the Activity’s **performedBy** association. (See Section 3.19.1.12, “ProcessRole,” on page 3-241.)

Hence an Activity represents an action that is either described by a further decomposition in the form of a CompoundTask or it represents and action that is performed by objects bound to ProcessRoles either statically, or at runtime as the Activity enters the Running state.

An Activity may also be associated via the usesArtifact and responsibleFor associations to one or more ProcessRoles. These ProcessRoles will be bound to Objects at run time as the Activity enters the Running state.
An Activity’s PortUsages representing InputGroups (input PortUsages), which contain ProcessPortConnectors representing ProcessFlowPorts (input ProcessPortConnectors), are the alternative means by which the Activity may supply data to these mechanisms to initiate some action.

PortUsages representing synchronous InputGroups owned by an Activity instance represent different initializations, and only one of these will ever be enabled, at which time the Activity instance will begin its execution.

An Activity instance must be in the Running state before it can use any data in input PortUsages (synchronous or asynchronous) from its containing Activity instance.

If no Synchronous input PortUsages are present, then the Activity will be initialized as part of the initialization of its container Activity. This will allow it to receive asynchronous inputs as soon as they propagate into the container Activity.

When an Activity is performedBy a ProcessRole which has not yet been bound, the ProcessRole will be bound to an appropriate Object during the initialization of the Activity. The binding for the Role will last at least for the duration of the life time of the Activity, but the Object it binds to may exist before the binding is created, and may live longer than the binding. Once bound, the Role will persist until all other Activities to which it is associated have completed.

Asynchronous input PortUsages owned by an Activity represent the means by which the Activity may accept input values during its active life time. When an Activity is in the NotStarted state (none of its synchronous input PortUsages is enabled) all data values that arrive at a ProcessPortConnector in an asynchronous PortUsage will be kept in that Port Connector only up to its multiplicity’s upper bound. Additional values will cause discarding. However, once the Activity enters the Running state the sets of correlated Inputs will be consumed by the Activity.

**Note** – This behavior trades off the resource savings of keeping asynchronous values only up to and including the slots defined by an Input’s multiplicities against the ability to queue all asynchronous flows on behalf of Activities yet to be enabled. The problem is that in many process definitions, choices are made about which path a process will take, leaving many Activities’ input PortUsages only partially satisfied and unable to ever become enabled. In a long-lived Process this may mean that large numbers of data values arriving at asynchronous Inputs will be queued, never to be consumed by that Activity.
Figure 3-50  State Machine describing execution of Activities and CompoundTasks.

Runtime Semantics: Figure 3-50 shows the state machine for an Activity instance. When an Activity is created, only the resources required to enact the PortUsage behavior of the Activity are created. The Activity then enters the NotStarted state. In this state the Activity may accept Flows at its input ProcessPortConnectors.

Once one of its synchronous input PortUsages is enabled (or it has no synchronous input PortUsages), ProcessRole binding is performed (as specified for ProcessRole in Section 3.19.1.12, “ProcessRole,” on page 3-241).

Then, if the Activity uses a CompoundTask that is a non-empty Composition, all the resources to represent the contained DataFlows, Bindings and nested Activities are allocated and all nested Activities are created. The Activity now enters the Running state.

An Activity instance enters the Completed state when none of its contained Activity instances that have synchronous output PortUsages containing values (that are not also exception PortUsages) are in the Running state and there are no DataFlows that are in the process of delivering their data (which could then trigger the running of another Activity). Note, this means that not all contained Activities need to have executed, only that none (that have synchronous output ProcessMultiPorts) are running. This results in a quiescent model for completion.

Alternatively, if an Activity instance has an exception PortUsage that is satisfied, then all Activity instances that are contained by this Activity instance and are in the Running state are aborted. The Activity will then satisfy the quiescent model completion criteria just outlined.

An Activity instance enters the Completed state, if a satisfied synchronous output PortUsage is enabled. If there is more than one satisfied synchronous output PortUsage, then the choice of which one to enable is arbitrary. If there is no synchronous output PortUsage that is satisfied, then the Activity instance’s system ExceptionGroup is enabled.
If a nested Activity instance contained by an Activity enters the Completed state with an exception PortUsage enabled and the exception is unhandled (see Section 3.19.1.11, “ExceptionGroup,” on page 3-240 for the definition of handled and unhandled ExceptionGroups), then the containing Activity instance’s system ExceptionGroup is enabled.

If an Activity instance is aborted, it terminates all of its contained Activity instances and enters the Aborted state.

If the Activity uses an empty Composition it must have a performedBy link to a ProcessRole, which will now be bound, and the Activity instance enters the Running state. While in the Running state, values from enabled input ProcessPortConnector instances may be consumed. In most cases this will mean that the PortUsage that was enabled has a collection of input Parameters for a method on the Object bound to the performer ProcessRole, which will be invoked. The return of the method will place values into an output PortUsage (representing an OutputGroup or ExceptionGroup), which will enable that PortUsage.

The Activity instance enters the Stopped state when one of its synchronous OutputGroup instances is enabled. If this is an ExceptionGroup instance, then it enters the Aborted state, otherwise it enters the Completed state.

**UML base element(s) in the Profile and Stereotype**

ClassifierRole stereotyped as <<Activity>>

**Fully Scoped name**

ECA::BusinessProcess::Activity

**Owned by**

CompoundTask

**Inheritance**

ECA::CCA:: ComponentUsage
  Activity

**Properties**

**Associated elements**

*uses (from ComponentUsage)*

An Activity is always associated with a CompoundTask via the uses association

*performedBy*

An Activity with an empty CompoundTask Composition must be linked to a single ProcessRole via the performedBy association.
usesArtifact
An Activity may require access to Objects via a ProcessRole to use as a passive
to as a passive
resource. Its usesArtifact association indicates the Roles it uses for this purpose.

responsibleFor
An Activity in a BusinessProcess may be performedBy a ProcessRole that does so on
behalf of another Role or Roles that are responsible for the Activity. The
responsibleFor association allows these Roles to identify Object representing
responsible parties.

Constraints
[1] An Activity that uses a CompoundTask definition with no internal Composition
must have a performedBy link.

3.19.1.3 BusinessProcess

Semantics
A BusinessProcess defines the ProcessComponent view of a process definition that
coordinates a set of related Activities. It defines a complete business process which can
be invoked from another CCA Composition, usually using OperationPorts which are
connected via DataFlows (a subtype of CCA Flow) to the ProcessPortConnectors of
the Activities which it contains. In other words a BusinessProcess is an ordinary
ProcessComponent on the outside, and a CompoundTask on the inside.

**Constraints**

N/A

### 3.19.1.5 ProcessFlowPort

**Semantics**

ProcessFlowPort represents data used in CompoundTask input/output.

**Runtime Semantics:** A ProcessFlowPort instance (represented by a ProcessPortConnector on an Activity) is **satisfied** when it has at least multiplicity_lb values, otherwise it is **unsatisfied**. It may not have more than multiplicity_ub values.

If a ProcessFlowPort instance is the sink of more than one DataFlow, then data values for that instance can be supplied by any one of those DataFlows up to the upper bound its multiplicity. In the default case of a multiplicity of {1,1} this implies OR semantics.
If more values are supplied than the multiplicity’s upper bound, the ProcessFlowPort instance’s collection remains at the size of the upper bound, and some arbitrary set of values are discarded.

When a ProcessFlowPort instance is enabled and its containing CompoundTask instance (represented by an Activity) is in the Running state, it transmits its values using all the associated DataFlows (AND semantics) as appropriate. If the ProcessFlowPort instance is contained by an asynchronous InputGroup instance, it then discards its values and resets its state to unsatisfied or satisfied according to its multiplicity.

**UML base element(s) in the Profile and Stereotype**

Class stereotyped as <<ProcessFlowPort>>

**Fully Scoped name**

ECA::BusinessProcess::ProcessFlowPort

**Owned by**

ProcessMultiPort

**Inheritance**

ECA::CCA::FlowPort

ProcessFlowPort

**Properties**

multiplicity_lb : short

multiplicity_ub : short

The multiplicity of a ProcessFlowPort instance allows it to act as a collection of data values of the same type. A multiplicity is expressed as a lower-bound, upper-bound pair \{multiplicity_lb, multiplicity_ub\}, where -1 is used in the upper bound to indicate infinity. The default multiplicity is \{1,1\} which represents a singleton collection.

**Associated elements**

ECA::CCA::DocumentModel::DataElement

A ProcessFlowPort is optionally associated with a DataElement by the type association, which is inherited from FlowPort. A ProcessFlowPort that does not have an associated type can be thought of as a control point. That is, the values handled by these ProcessFlowPorts are like objects that have identity but no attributes. They can be used, in conjunction with DataFlows, to describe control flow constraints that do not involve data values.
Constraints

3.19.1.6 ProcessPortConnector

Semantics
A ProcessPortConnector represents the usage of a ProcessFlowPort in the context of a CompoundTask.

A ProcessPortConnector may be associated with zero or more DataFlows via the outgoing association.

incoming (from Node)
A ProcessPortConnector may be associated with zero or more DataFlows via the incoming association.

Constraints

### 3.19.1.7 DataFlow

**Semantics**

A DataFlow represents a causal relationship in a business process. The source of the DataFlow must “happen” before the sink of the DataFlow. DataFlows also propagate data values between causally related ProcessPortConnectors. In the case that a DataFlow connects two ProcessPortConnectors in synchronous ProcessMultiPorts, the implication is that the Activities occur in strict temporal sequence.

**Runtime Semantics:** A DataFlow instance is created when its containing CompoundTask instance is created.

The enabling of the source of a DataFlow causes the enabling of the DataFlow, which then propagates the values from the source ProcessPortConnector to the sink ProcessPortConnector. The sink ProcessPortConnector may then discard values as necessary if its multiplicity upper bound is reached.

**UML base element(s) in the Profile and Stereotype**

**Fully Scoped name**

ECA::BusinessProcess::DataFlow

**Owned by**

CompoundTask

**Inheritance**

ECA::CCA::Connection

  DataFlow

**Properties**

**Associated elements**

**Constraints**

[1] A ProcessPortConnector is a source of a DataFlow. A DataFlow has exactly one source ProcessPortConnector, but a ProcessPortConnector can be the source of zero or more DataFlows.

[2] A ProcessPortConnector is a sink of a DataFlow. A ProcessPortConnector has exactly one sink ProcessPortConnector, but a ProcessPortConnector can be the sink of zero or more DataFlows.
[3] The ProcessPortConnector that is the source of a DataFlow must be contained (indirectly) by the same CompoundTask as the DataFlow, and must be either:

- a ProcessPortConnector representing a ProcessFlowPort of an InputGroup of the CompoundTask; or
- a ProcessPortConnector representing a ProcessFlowPort owned by a PortUsage representing an OutputGroup of a CompoundTask used by an Activity directly contained by the DataFlow’s containing CompoundTask.

[4] A ProcessPortConnector that is the sink of a DataFlow must be contained (indirectly) by the same CompoundTask as the DataFlow, and must be either:

- a ProcessPortConnector representing a ProcessFlowPort of an OutputGroup of the CompoundTask; or
- a ProcessPortConnector representing a ProcessFlowPort owned by a PortUsage representing an InputGroup of a CompoundTask used by an Activity directly contained by the DataFlow’s containing CompoundTask.

The well-formed-ness rules above can be considered as reading “DataFlows cannot cross the boundaries of CompoundTasks.” Figure 3-51 shows three illegal DataFlows (Note how the illegal DataFlows cross Task boundaries).

![Figure 3-51 Illegal DataFlows crossing Task boundaries.](image)

[5] The type of the ProcessFlowPort represented by the source ProcessPortConnector of a DataFlow must be the same as (or coerce-able to) the type of the ProcessFlowPort represented by the sink ProcessPortConnector of a DataFlow. Coercible includes converting a value of type T to a member of type collection<T> and vice versa.

[6] DataFlows between ProcessPortConnectors owned by PortUsage representing synchronous ProcessMultiPorts within a CompoundTask should be acyclic; that is, things cannot happen in a circular order. (However, see Business Process Patterns in Section 3.22, “Process Model Patterns,” on page 3-270 for how to specify processes involving looping.)
3.19.1.8 ProcessMultiPort

Semantics

ProcessMultiPort represents a set of related ProcessFlowPorts used to describe the inputs and outputs of CompoundTasks. They act as a form of correlator for DataFlows.

Run-Time Semantics: As this section describes the semantics of ProcessMultiPorts, owned by CompoundTasks, we use the terminology ProcessMultiPort instance to mean a PortUsage representing a ProcessMultiport owned by an Activity, which we call a CompoundTask instance. In the same way the term ProcessFlowPort instance is used to mean a ProcessPortConnector contained by the PortUsage representing the ProcessMultiport.

A ProcessMultiPort instance is satisfied when all of its contained ProcessFlowPort instances are satisfied (AND semantics), otherwise it is unsatisfied.

If a ProcessMultiPort instance is satisfied then it may be enabled. However, at most one synchronous InputGroup instance of a CompoundTask instance and one synchronous OutputGroup instance of a CompoundTask instance may be enabled and, once enabled, must remain in that state. An asynchronous ProcessMultiPort instance does not have these constraints. It will enable its ProcessFlowPort instances whenever it becomes enabled allowing them to transfer their contents and reset their state to unsatisfied (or satisfied if their multiplicity_lb is zero). This semantics is described formally using the Protocol in Figure 3-52.

Figure 3-52  Example Protocol describing the behavior of ProcessMultiPorts.
UML base element(s) in the Profile and Stereotype

Class stereotyped as <<ProcessMultiPort>>

Fully Scoped name

ECA::BusinessProcess::ProcessMultiPort

Owned by

CompoundTask

Inheritance

ECA::CCA::MultiPort
  ProcessMultiPort

Properties

synchronous : boolean (from Port)

A value of TRUE indicates that this ProcessMultiPort represents either parameters that may be used to trigger a CompoundTask instance to enter the Running state, or results that are available when the instance enters the Stopped state.

A value of FALSE indicates that while the CompoundTask instance is in the Running state, the ProcessMultiPort may either asynchronously consume one or more sets of data, or asynchronously emit one or more sets of data.

Associated elements

ProcessFlowPort

A ProcessMultiPort provides a correlation framework for a number of ProcessFlowPorts.

Constraints

3.19.1.9 InputGroup

Semantics

InputGroup is a specialization of ProcessMultiPort. It is a container for a number of ProcessFlowPorts which are the inputs to a CompoundTask.

Runtime Semantics: The InputGroup implies special semantics for the lifecycle of an Activity using the CompoundTask definition that owns it when its synchronous attribute is TRUE. In this case the InputGroup must be enabled before the Activity may enter its Running state.

ECA::BusinessProcess::InputGroup

Owned by
CompoundTask (via its base class Composition)

Inheritance
ECA::CCA::ComponentSpecification::ProcessMultiPort
  InputGroup

Properties

Associated elements

Constraints

3.19.1.10 OutputGroup

Semantics
OutputGroup represents a possible outcome of a CompoundTask; it provides data values associated with that outcome. In the case of a synchronous OutputGroup it also serves as an indication that an Activity using the CompoundTask definition to which the OutputGroup belongs has entered the Stopped state.

OutputGroup models a collection of data values produced by a CompoundTask.

Runtime Semantics: The OutputGroup implies special semantics for the lifecycle of an Activity using the CompoundTask definition which owns it when its synchronous attribute is TRUE. In this case the Activity must be in its Stopped state before the OutputGroup may be enabled.

UML base element(s) in the Profile and Stereotype
Class stereotyped as <<OutputGroup>>

Fully Scoped name
ECA::BusinessProcess::OutputGroup

Owned by
CompoundTask
Properties

Associated element

Constraints

3.19.1.11 ExceptionGroup

Semantics

ExceptionGroup represents the outcome of a CompoundTask that failed to complete its function. In a CompoundTask, an Activity’s ProcessPortConnectors representing the ProcessFlowPorts of ExceptionGroup can be handled either by an exception handler (an Activity) to which the Port Connectors have DataFlows, or by an ExceptionGroup of the containing CompoundTask to which it has DataFlows. If, at runtime, an Activity’s ExceptionGroup is not handled and the Exception is enabled, then it will be propagated. That is, the containing CompoundTask instance’s system Exception will be enabled (which consequently causes the CompoundTask instance to abort its contained Activities and terminate in the Aborted state).

Figure 3-53  An ExceptionGroup that is handled by an Activity

Figure 3-54  An unhandled ExceptionGroup that will be propagated if it is enabled at runtime.
UML base element(s) in the Profile and Stereotype
Class stereotyped as <<ExceptionGroup>>

Fully Scoped name
ECA::BusinessProcess::ExceptionGroup

Owned by
CompoundTask

Properties
Associated elements
Constraints

3.19.1.12 ProcessRole

Semantics
ProcessRole defines a placeholder for concrete ProcessComponents that perform an Activity or that are used in the performing of an Activity. It defines a placeholder for behavior in a context. ProcessRole is a subtype of ComponentUsage with some qualifying attributes. The owner of a ProcessRole is a CompoundTask and the behavior of the ProcessRole becomes part of the behavior of Activities to which it is associated. The uses association of a ProcessRole (inherited from ComponentUsage) defines the type of ProcessComponent that is required to be bound to the placeholder.

Runtime Semantics: When an Activity is enabled, binding of any associated unbound ProcessRole instances ensues based on the values of the selectionRule and creationRule expressions. Note that some ProcessRole instances may have been bound previously due to an association with another Activity that has already been enabled so no further binding is needed.

If both the selectionRule and creationRule expressions are empty, then it is left up to the Activity itself to perform binding. Otherwise, binding takes place as follows:

Binding of an unbound ProcessRole begins by determining the candidate instances. These are the set of ProcessComponent instances with a compatible type and that satisfy the selectionRule. The selectionRule may refer to the values of the input ProcessPortConnectors of any of the ProcessRole's associated Activities. It is incumbent on the modeler to ensure that the selectionRule is well-formed in the face of attributes that may not yet have values.

If there are no candidate instances, and the creationRule expression is non-empty, it will be used to generate a new candidate instance (or instances if the expression returns multiples).
One of the candidate instances will then be bound to the ProcessRole. If there are no candidate instances, the containing Activity instance will have its system ExceptionGroup enabled.

We note that something akin to the OMG Trader service can be used for this binding process. Also, the bound entity may be a proxy for a person such as a worklist in a workflow execution environment.

**Inheritance**

ECA::CCA::ComponentUsage

    ProcessRole

**UML base element(s) in the Profile and Stereotype**

ClassifierRole stereotyped as <<ProcessRole>>

**Fully Scoped name**

ECA::BusinessProcess::ProcessRole

**Owned by**

CompoundTask

**Properties**

*selectionRule*

An expression describing the set of entities that may be bound to this ProcessRole.

*creationRule*

An expression describing how to create a new entity that may be bound to this ProcessRole.

**Associated elements**

ProcessComponent: the uses association, inherited from ComponentUsage, indicates a type of ProcessComponent (an abstract ProcessComponent). A concrete instance of this type must be bound to the ProcessRole at runtime.

Activity: these may be associated with ProcessRoles by one or more of the following: performedBy and/or usesArtifact and/or responsibleFor.

**Constraints**

[1] The ProcessComponent at the opposite end of the uses association must be abstract.
3.19.1.13 Performer

**Semantics**

A Performer ProcessRole is specifically for identifying an Entity that can perform the Activity to which it is associated.

**Inheritance**

ECA::CCA::ComponentUsage
   ProcessRole
   Performer

**UML base element(s) in the Profile and Stereotype**

 ECA::CCA:: Connection
 «DataFlow»

Instantiation in a model
Concrete

Semantics
Corresponds to the element of named "DataFlow" in the metamodel.

«DataFlow» stereotyped AssociationRoles will be connected to the source and target «PortConnector» ClassifierRole through AssociationEndRole. A DataFlow may either connect a generic ProcessComponent PortConnector on a BusinessProcess to a ProcessPortConnector of one of its Activities or it may connect two ProcessPortConnectors when owned by a CompoundTask.

Relationships
As per base stereotypes

Tagged Values
N/A

Constraints expressed generically
At least one AssociationEndRole of a DataFlow must be a ProcessFlowPort.

A DataFlow may only connect the following kinds of ProcessFlowPorts. "CT" is short for CompoundTask, and indicates ProcessPortConnectors representing the ProcessFlowPorts contained by its three kinds of ProcessMultiPorts. The other three labels refer to any ProcessPortConnectors on an Activity in the CompoundTask's Composition.
These connection constraints can also be expressed as follows:

A ProcessPortConnector representing a ProcessFlowPort owned by an InputGroup of the CompoundTask which is represented by the Collaboration may not be the target of any DataFlows.

A ProcessPortConnector representing a ProcessFlowPort owned by an OutputGroup (including ExceptionGroups) of the CompoundTask which is represented by the Collaboration may not be the source of any DataFlows.

A ProcessPortConnector owned by any Activity in the Collaboration which represents a ProcessFlowPort owned by an OutputGroup (including ExceptionGroups) may not be the target of any DataFlows.

A ProcessPortConnector owned by any Activity in the Collaboration which represents a ProcessFlowPort owned by an InputGroup may not be the source of any DataFlows.

3.20.2.6 Represents in CompoundTask and BusinessProcess

The metamodel element Composition (the "inside" of a CompoundTask or BusinessProcess) is represented by a UML Collaboration.

A ProcessPortConnector is mapped to a ClassifierRole.

The "Represents" relationship linking a ProcessPortConnector with a ProcessFlowPort, is represented in UML as the UML relationship between a ClassifierRole and its base Classifier.

3.21 Notation for Activity and ProcessRole

As shown in Figure 3-56, an Activity is represented similarly to a ProcessComponent. If the Activity uses a CompoundTask that is not primitive (i.e., the Composition is non-empty and the isPrimitive attribute is false), then the ProcessComponent rectangle has a drop-shadow as shown in Figure 3-57.
Figure 3-56  Activity with synchronous and asynchronous InputGroups, an OutputGroup and an ExceptionGroup.

Figure 3-57  Activity that is involves creation of a Composition of nested Activities, etc.
Figure 3-58  A CompoundTask showing its composed Activities.

The lollipops represent ProcessFlowPorts and the boxes surrounding them represent ProcessMultiPorts. InputGroups appear on the left-hand side of the Activity and OutputGroups appear on the right-hand side. Rectangular tabs are used to indicate synchronous ProcessMultiPorts, rounded tabs are used to indicate asynchronous ProcessMultiPorts. Triangular or bevel-edged tabs are used to indicate ExceptionGroups, which are a kind of OutputGroup, and hence always appear on the right.

ProcessRoles are drawn as octagons and are associated with Activities by either the performedBy association for Performer roles, the usesArtifact association for Artifact roles, or the responsibleFor association for ResponsibleParty roles. These associations are drawn as a solid line annotated with the association name. See Section 3.19.1.12, “ProcessRole,” on page 3-241 for more detail on the definition and usage of ProcessRoles. It should be noted that a single ProcessRole may be an artifact role in one association and a performer role in another association at the same time. Additionally, an Activity that has a uses association to a CompoundTask with composed Activities, DataFlows and ProcessRoles, may not have a performedBy association to a ProcessRole.

3.22 Process Model Patterns

The rest of this section describes various patterns of common usage and associated special notation that may be useful when using the ECA Process Model. We first describe the pattern in terms of its normal notation, possibly with parameterized parts, and in some cases then provide alternative shorthand notations.

We begin with some simple patterns then move on to more complex patterns involving looping. In general, arbitrary loops in a business process specification can be quite subtle in their behavior, especially in conjunction with concurrent threads. It is for this
reason that we restrict an Activity with synchronous DataGroups to executing once only. The looping patterns presented here avoid these problems since they are always defined in terms of an underlying recursive invocation structure.

It should be noted that the UML template notation, and the Patterns Framework introduced in Chapter 4, are not sufficient to express the complexity required by these patterns, since they usually consist of a CompoundTask parameterized by an Activity that will have some unknown number of ProcessMultiPorts and ProcessFlowPorts. When instantiating such a template with respect to a particular Activity, the CompoundTask needs to have corresponding ProcessMultiPorts and ProcessFlowPorts connected by Flows to the equivalent ports on the Activity argument to the template.

3.22.1 Timeout

Often we will want to have an Activity timeout after some period. The pattern shown in Figure 3-59 illustrates how we might do this. The Activity and timer are started at the same time. If the timer finishes and sends a message on its asynchronous OutputGroup before the Activity finishes, then the ExceptionGroup will be enabled and the CompoundTask will terminate, thus terminating all contained Activities. On the other hand, if the Activity finishes first, the CompoundTask will terminate without waiting for the timer (since it has no synchronous OutputGroups).

A shorthand notation for this pattern is given in Figure 3-60. This notation may also include a duration parameter, or absolute time parameter, which would be provided as input to the underlying timer activity.
Note we do not mandate any particular implementation for the timer task, we merely posit its existence. It would be up to the modeler to have an appropriate performedBy association, or for particular mappings to provide a suitable implementation.

### 3.22.2 Terminate

We may wish to be able to terminate an Activity before it has completed of its own accord. The pattern shown in Figure 3-61 illustrates how an Activity can be wrapped to support an additional asynchronous InputGroup that, on reception of a message, will result in the activity being terminated and an exception being thrown.

That is, if a message is sent to the asynchronous InputGroup of the CompoundTask, then it will immediately flow to the CompoundTask’s ExceptionGroup causing the CompoundTask to terminate, thus terminating the contained Activity.

There is no suggested shorthand notation for this pattern. However, tools may wish to support the implicit inclusion of an appropriately labeled asynchronous InputGroup and corresponding ExceptionGroup on any arbitrary Activity.
3.22.3 Activity Preconditions and Activity Postconditions

Sometimes it may be desirable to add a precondition to the InputGroup of an Activity, or the OutputGroup of a CompoundTask, to further constrain the enabling of the InputGroup/OutputGroup. For example, there may be multiple DataFlows to an input, but we wish to ignore any values that fall outside a given range. Figure 3-62 illustrates how one might attach such a guard constraint where x and y are attributes of the DataGroup (or perhaps even attributes of their contained DataElements).

Figure 3-63 shows an equivalent CompoundTask to that of Figure 3-62 but using explicit filter Activities.

If a filter Activity does not produce enough outputs to satisfy the multiplicity requirements of the Activity it is guarding, then the Activity will not start. As can be seen from Figure 3-63, if neither filter is satisfied, then Activity ‘A’ will never run, so
the CompoundTask instance will satisfy its completion criteria (quiescence) without either OutputGroup being satisfied which causes its system ExceptionGroup to be enabled.

In a similar way, we may also attach a post-condition to an Activity’s OutputGroup to ensure that the result of the Activity satisfies some condition. This is shown in Figure 3-64.

Figure 3-64  Post-conditions on OutputGroups of Activities.

Figure 3-65 shows an equivalent CompoundTask to that of but using explicit filter Activities that have a ‘success’ OutputGroup and a ‘fail’ ExceptionGroup. Thus, if the postcondition does not hold, the CompoundTask’s system ExceptionGroup will be enabled.

Figure 3-65  An equivalent model to that of , using condition tasks.
3.22.4 Simple Loop

The pattern shown in Figure 3-66 shows how we might repeatedly invoke an Activity until a particular OutputGroup is enabled. If the cardinality of the Output in the loop CompoundTask is 0..*, then all the results of the Activity will be collected. If it is 0..m for some finite m, then some subset of those results will be collected.

In this case, we assume that the exit condition and the loop action are combined into a single Activity, possibly via a CompoundTask. Normally this will not be the case, however, and the more general patterns described in Section 3.22.5, “While and Repeat-Until Loops,” on page 3-276 through Section 3.22.7, “Multi-Task,” on page 3-278 will be used.

A special-case shorthand notation for such a loop is shown in Figure 3-67. The looping flow indicates that simple recursion is taking place. Any OutputGroup containing a ProcessPortConnector that is the source of a looping flow may only be the source of flows to a single InputGroup.

![Figure 3-66 Simple Loop Pattern](image1)

![Figure 3-67 Simple Loop Notation](image2)
### 3.22.5 While and Repeat-Until Loops

#### Figure 3-68  While Loop Pattern

In Figure 3-68 we see a more general ‘while’ loop pattern with separate exit test and loop body, and Figure 3-69 shows a slightly different pattern that results in a ‘repeat-until’ loop. The ‘while’ and ‘until’ Activities represent some kind of boolean expression evaluation engine.

#### Figure 3-69  Repeat/Until Loop Pattern
As for the Simple Loop, these loops could be drawn as shown in Figure 3-70 and Figure 3-71 respectively.

**Figure 3-70** While Loop Notation

**Figure 3-71** Repeat-Until Notation

### 3.22.6 For Loop

The pattern in Figure 3-72 shows how to do a for-loop with a generalized initialization step, loop test, and loop body as popularized by the C, C++, and Java languages. Note that the inner loop is the while-loop pattern and hence the special-case notation for while-loops can be used.

**Figure 3-72** For Loop Pattern
3.22.7 Multi-Task

Figure 3-73  Pattern for a multi-task

The pattern in Figure 3-73 shows how to process a collection of items in parallel and collect the results. The split activity takes a collection of items and splits them into a head and a tail. The head is passed to the activity for processing, while a concurrent recursive invocation of the loop is initiated to process the tail. If, however, the collection is empty, then the split’s other OutputGroup is enabled and the loop CompoundTask finishes. No explicit flow from this OutputGroup to the CompoundTask’s OutputGroup is required since all it’s Outputs will be satisfied with a zero cardinality.

Intuitively, what happens when this pattern executes is as follows. When a collection of items is passed in to the multi-task pattern, a set of concurrent loops and activities is spawned, one pair for each item in the collection. The activity processes an item, and the concurrent loop recursively handles the other n-1 items.

Note that if an Activity processing an item throws an exception, it is caught and passed to a second Output in the OutputGroup. This means that a single failed Activity doesn’t cause all the other Activities to be terminated and the completed activities to throw away their results. This is especially useful in the case where we might wish to apply the timer pattern to the Activity.

No shorthand notation for multitask is suggested.
3.23 Full Model

The diagram below represents the full metamodel for the Business Process profile.

Figure 3.74  Combined MOF model of Process
Section VI - The Relationships Profile

The Relationships profile describes the extensions to the UML core facilities to meet the need for rigorous relationship specification in general and in business modeling and software modeling in particular.

3.24 Requirements

3.24.1 Introduction

This section describes extensions to the UML core facilities that support the need for rigorous relationship specification in general and in business modeling and software modeling in particular. In this context, the most important and most interesting aspects of behavior are in the relationships between participants rather than in the behavior of participants. Therefore clear, concise and rigorous specification of relationship semantics is of utmost importance.

Note that multiplicities are not the most important or most interesting properties of relationships. Property determinations are much more important for the semantics of a relationship, and distinguish among different kinds of relationships. The fragments of relationship invariants about property determination represent an essential fragment of those elusive “business rules” that are the backbone of a good specification and that should never be only “in the code.”

At the same time, it is very desirable to discover and specify – rather than reinvent – those kinds of relationships that are encountered in all specifications, so that reuse at the specification level becomes possible. Such generic relationships extend the set of reusable constructs that already exist in UML.

This section includes somewhat simplified examples that demonstrate the practical usage of these relationships.

The section also provides advice for choosing and using a subset of UML for business modeling such a that the business models represented in terms of this subset will be readable and understandable by all stakeholders, specifically, business subject matter experts, analysts, and developers (as well as managers). The generic relationships described here are among the most important constructs of this subset.

The UML extensions described in this document were not invented from scratch; they were reused from existing international standards and based on existing modeling practice. The material about generic relationships presented here is based on long-term

4. “Behavior must be described at the system level, not the object level: all interesting behavior is in the relationships between objects, and it is impossible to understand behavior of the system by looking only at the behavior of its parts.” (From the keynote of Anthony Hall at Requirements Engineering ‘97)

5. In most cases, the multiplicities follow from the generic relationship invariant and therefore do not need to be explicitly shown in the diagram: the Stereotype takes care of that. Such diagrams are less cluttered.
experience in modeling in various areas (telecommunications, finance, insurance, document management, business process change, etc.) described in [12], [10], [14], [17] (Appendix A) and elsewhere.

Similarly to UML, we use invariants to specify the semantics of various kinds of relationships. UML 1.4 Section 2.3.2 states, “The static semantics ... are defined as a set of invariants of an instance of the [association].... These invariants have to be satisfied for the construct to be meaningful.”

The approach presented here is extensible, and if it appears that in a particular business (or a set of applications) additional generic relationships are needed and useful, then they may be precisely and explicitly defined and added in a manner similar to the definitions provided here.

Generic relationships provide concepts and constructs that permit UML to be used for specification of businesses and systems in a more rigorous manner than (and without restrictions currently imposed by) the base UML 1.4. Generic relationships provide for explicit specification of relationship semantics in class diagrams, so that a line between boxes – even a named line! – will not be considered an adequate relationship specification. Names by themselves do not determine semantics; if a name is used then it has to be precisely defined in the same manner that generic relationship stereotype names like “Assembly” are defined in this document.

The semantics of a class diagram is in its structure – the collections of “lines” – and so it has to be appropriately defined and represented graphically. Fortunately, UML provides adequate extension facilities to satisfy this goal.

3.24.2 Non-Binary Relationships

In many cases, a relationship – such as subtyping or UML aggregation – is defined between more than two participants. This happens because the invariant that defines the relationship refers to all its participants rather than just to two of them. Therefore, several binary relationships are not equivalent to one non-binary. The joint properties of these binary relationships (formalized in the invariant referring to all of them) would not be specified in the former case. More specifically, such invariants often describe how the properties of one relationship participant – such as the “whole” – are determined on the basis of the (joint) properties of the other relationship participants – such as its “parts.”

---

6. A combination of two interrelated lines required by the currently existing UML metamodel is an exception; specifically, an association line that simply mandates a link is acceptable, but only if it is paired with a <<Reference>> dependency line. <<Reference>> is defined later in this document.

7. After a precisely defined relationship was named, the name may be used again and again without repeating the semantics. Such a name may be used instead of the semantics (and vice versa).
Based on substantial modeling experience – see also the examples below – we consider most relationships to be asymmetric, and more specifically, we state that an asymmetric relationship relates a source type to a non-empty set of target types. As a familiar example, in a generic Aggregation relationship (which corresponds to the RM-ODP composition), the “whole” is related to a “collection of parts,” and the specific invariant determines the kind of this relationship. In other words, only a collection of all AssociationEnds jointly realizes an Association.

As a more specific consequence, visible in Figure 3-75, we must clearly and explicitly distinguish between two or more aggregations for the same whole (which are not interrelated by any invariant) and a non-binary aggregation defined by a specific (property determination) invariant.

Since UML version 1.4 requires an Aggregation to be binary only, we have to remove this restriction (e.g., from UML 1.4, Section 2.5.3, Rule 3; also, UML 1.4, Sections 3.3 and 3.43.3 are affected since an “aggregation tree” may have its own semantics and is not just a presentation option; etc.). After that, we can apply the “Aggregation” Stereotype and its subtypes to Association (note that the property determination invariant is explicitly used to define this Stereotype).

Appropriate icons — that can represent directionality — are essential for a better graphical representation. Clearly, there is no need to have an icon for every conceivable modeling element, but the already existing (asymmetric!) UML icons representing a relationship (e.g., diamond for aggregation or triangle for subtyping), together with a Stereotype abbreviating the invariant of the relationship type, solve the problem, as seen from the examples.

### 3.24.3 Example: Mutually Orthogonal Non-Binary Aggregations

Figure 3-75 demonstrates the need for non-binary aggregations, for different (mutually orthogonal) aggregations for the same whole, and for an asymmetric representation of non-binary relationships in general.

Currently, UML 1.4 restricts aggregations to being binary; this restriction does not permit clear representation of business requirements, specifically the invariants, like the ones shown in the example. Similarly, UML treats all parts for the same aggregate in an equal manner; this restriction does not permit grouping only those parts that “belong together” because those parts are referred to in the same aggregation invariant for property determination.

---

8. This is based on the mathematical concept of a relation used in formal specifications; see, for example, [PST91].

9. RM-ODP [RM-ODP] defines a composition of objects as follows: “A combination of two or more objects yielding a new object, at a different level of abstraction. The characteristics of the new object are determined by the objects being combined and by the way they are combined.” Similarly, other <X>s (such as behaviors) can be composed.
UML also does not currently specify how to show mutually orthogonal (independent) aggregations on a diagram. Such aggregations appear quite often, in particular when different viewpoints have to be considered. Finally, the current UML represents non-binary associations in a way that does not clearly distinguish between association source and target. Such distinction is needed for non-binary Aggregation Associations.

The example shows how UML is extended to deal with these issues by using the generic relationships described in this document. The diagram below (see Figure 3-75) demonstrates two aggregations— a content-based and a logical layout-based decomposition of an OMG Domain Task Force (DTF) specification document.

![Figure 3-75 UML Extensions Representing Multiple Viewpoints](image)

The two decompositions in Figure 3-75 show two different viewpoints used to better understand different aspects of such a document. Clearly, concerns used in these viewpoints are different and therefore ought to be distinguished explicitly.

On the one hand, a DTF specification document, from the content-based viewpoint, is decomposed into fragments of general nature, fragments that deal with domain-specific issues, and fragments that deal with CORBA-specific issues. In accordance with OMG requirements, these fragments have to be present in a document in order for it to be a DTF specification; this explains the <<Assembly>> Stereotype (defined below).

---

10. This traditionally has been represented graphically as a “diamond” attached to the “whole”. Other representations are certainly possible.

11. Presenting (abstractions of) the different aggregations of the same whole in the same diagram provides a roadmap that enhances understanding of complex specifications. As a more specific example, four different ways to decompose a Trade were deemed necessary by the business experts in an exotic option environment.
Further, the fragments may exist independently of the existence of the DTF specification document, as often happens when the specification authors reuse some of their already existing document fragments. Therefore the diamond is white rather than black; this aggregation is shared.

On the other hand, the same document is decomposed from the logical layout-based viewpoint into fragments that represent text and fragments that represent diagrams. Again, the <<Assembly>> Stereotype is used since OMG requires that such documents contain both text and (UML) diagrams. And again, these fragments may exist independently of the existence of the document itself.

There is no 1:1 relationship between a fragment of the content-based decomposition and a fragment of the logical layout-based decomposition. Moreover, in a more detailed specification it is possible to define reference relationships (see below) between some content-based fragments and some logical layout-based fragments. And for a specific DTF OMG document, it is possible to be more detailed about the nature of the content-based fragments, and also about the nature of their types.

From the above description it can be seen that this specification presents two <<Aggregations>> rather than five. The invariants that define these two aggregations clearly demonstrate this: for example, the value of the document property named “abstract” is determined jointly by the values of the content properties of the parts in the content-based aggregation, while the value of the document property named “number of pages” is determined jointly by the values of the properties “number of pages” of the parts in the logical layout-based aggregation. (It is possible to be more detailed and consider physical layout-based aggregation as well, but for simplicity the logical and physical layout-based aggregations were merged.)

Finally, observe that each relationship shown in the diagram above has an indication of its Stereotype (a “type name”) and its own name. The former may be sufficient if the modeler and the client believe that non-unique names are appropriate for the context and will not (ever!) lead to misunderstandings. However, the use of identifiers (i.e., names that uniquely distinguish a thing (in this case, a relationship) from another thing) is recommended. Of course, the stereotype is essential since it abbreviates the invariant for the particular kind of relationship.

12. Properties are, for simplicity, not shown in the diagram. At the same time, the designation of a relationship as an Aggregation requires, at an appropriate level of detail, to specify the property determination invariant of that specific relationship (e.g., of content-based). This invariant refers to the appropriate properties, and usually is not represented graphically.
3.24.4 Example: Multiple Subtyping

The simple example shown in demonstrates the need to be able to specify multiple subtyping hierarchies for the same supertype. As for any relationship, each subtyping hierarchy (with its subtypes) is defined by its invariant; and the invariant of one subtyping hierarchy is independent of the invariant of the other subtyping hierarchy (or hierarchies).

![Diagram of Multiple Subtyping Hierarchies for the Same Supertype](image)

In this example, an employee satisfies exactly one subtype in the *gender-related* subtyping hierarchy and at least one subtype in the *function-related* subtyping hierarchy. Thus, the *function-related* subtyping is overlapping: the employee may satisfy either one or both subtypes in this hierarchy at the same time. Clearly, the two subtyping hierarchies presented above are mutually independent. It means that the four subtypes shown in the diagram cannot be merged into one subtyping hierarchy: such merge would destroy the semantics represented there.

3.24.5 Other Relationship Requirements

The following additional important generic relationships (and their subtypes) have been defined in and elsewhere:

- **Reference**: A binary, asymmetric relationship in which the properties of instances of one type determine the properties of instances of another type.
3.25 Using UML to Address the Requirements: An Overview

Some of the required relationships can be represented in UML in a straightforward manner. UML 1.4 permits specification of multiple mutually independent (mutually orthogonal) subtyping hierarchies of the same supertype, as well as the specification of multiple subtypes of the same supertype in the same subtyping hierarchy\(^{13}\). This was demonstrated in the example above. In addition, some of the generic subtypes of composition may be presented using existing UML constructs (see below).

In UML a subtype hierarchy is called a *partition*\(^{14}\). A sub/supertype relationship is called a *Generalization*, which has one element in the role of parent and one in the role of child. A Generalization has a property called the *discriminator*. If two Generalizations have the same parent and the same discriminator, then they are part of the same partition.

A Generalization partition can be constrained to be *complete* or *incomplete* and, separately, to be *disjoint* or *overlapping*. If a partition is incomplete it means that there could conceivably be instances of the supertype that are not instances of any of the subtypes. Complete is the default. If a subtype hierarchy is disjoint it means that no instance of the supertype can be an instance of more than one of the subtypes. Disjoint is the default.

Therefore, in what follows, the generic subtyping relationship will not be discussed further (although its UML representation will be used in examples). The generic relationships for which UML extensions are presented include only aggregation, reference, and symmetric relationships. The representation of these generic relationships will be accomplished by extending the UML core elements “Association” and “Dependency.”

3.26 Formal Virtual Metamodel of the UML Extensions

A virtual metamodel (VMM) is a formal model of a package of extensions to the UML metamodel using UML’s own built-in extension mechanisms. UML’s primary extension mechanisms are *Stereotypes* and *TaggedValues*.

This VMM defines only Stereotypes. It does not define any TaggedValues. Figure 3-77 is a class diagram of the VMM. Stereotypes defined by the VMM are denoted by Classes boxes with the `<<stereotype>>` keyword. The fact that a Stereotype extends a

---

13. In this manner, it is possible to support the specification of dynamic typing, i.e., of a thing acquiring and losing type(s). A thing acquires a type when it acquires the properties (satisfies the invariant) of that type; and a thing loses a type when it loses the properties (no longer satisfies the invariant of) that type. As an example, consider a person acquiring and losing such types as employee, homeowner, stockholder, and so on.

14. Not to be confused with a “swim lane” partition in an activity graph
particular element of the UML metamodel is shown via a Dependency stereotyped <<baseElement>> that points from the Class box representing the Stereotype to a Class box representing the UML metamodel element.

Figure 3-77  Class Diagram of the Virtual Metamodel

3.26.1 Aggregations

3.26.1.1 Stereotype: Aggregation

Inheritance

Association
Aggregation

Instantiation in a model

Concrete
**Semantics**

For an Aggregation, the properties of one of the participants (of the source type) – also called the “whole” – are determined, in part, by the properties of the other participants – also called the “parts.”

The Aggregation properties captured by the Packet, Assembly, Subordination, and List Stereotypes described below are orthogonal to whether the aggregate’s AggregationKind is shared (corresponding to shared Aggregation) or composite (corresponding to hierarchical Aggregation).

**Tagged Values**

None

**Constraints**

**Constraints Expressed Generically**

*Invariant* - An aggregate (“whole”) type corresponds to one or more part types, and an aggregate instance corresponds to zero or more instances of each part type. There exists at least one property of an aggregate instance determined by the properties of its part instances. There exists also at least one property of an aggregate instance independent of the properties of its part instances.

**Note** – It is not possible to express all the semantics of Aggregation specified in the Invariant above – including the property determination semantics – in a way that can be rendered in OCL nor in a structured English that maps to OCL. The OCL constraints for Aggregation merely pin down the relationship of the Aggregation Stereotype to previously existing concepts about aggregation in the UML metamodel. On the other hand, the formal constraints for the sub-Stereotypes of Aggregation (Assembly, Subordination, etc.) in subsequent sections really do express the essential semantic distinctions that these more specific Stereotypes convey.

**Formal Constraints Expressed in Terms of the UML Metamodel**

**English**

*Invariant:* For exactly one of the participants in the Association, AggregationKind = shared or AggregationKind = composite.

**OCL**

```ocl
inv OneAggregate:
   self.connections->select (end | end.aggregation <> #none)
   ->size = 1
```

15. The UML specification makes no claim that all the semantics are expressed in OCL; it labels the OCL assertions only as well-formedness rules.
**UML Constraint Relaxed**

The following UML 1.4 constraint\(^{16}\) is relaxed, i.e. is not in force in this UML profile

**English**

**Invariant:** If an Association has three or more AssociationEnds, then no AssociationEnd may be an aggregation or composition. [RELAXED]

**OCL**

\[
\text{self.allConnections}\rightarrow\text{size} \geq 3 \implies \text{self.allConnections}\rightarrow\forall(\text{aggregation} = \#\text{none}) \quad --\text{RELAXED}
\]

**Diagram Notation\(^{17}\)**

An Aggregation uses the traditional UML aggregation diamond notation. When the Aggregation is non-binary, we do not use the standard UML notation for non-binary associations; instead, the line extending away from the aggregate and away from the diamond divides into branches, with each branch extending to one of the parts\(^{18}\) as shown in Figure 3-78 and Figure 3-79.

Multiplicities may be shown in the normal UML fashion and must be specified in the model for the model to be well formed. However, in most cases the specific sub-Stereotype of Aggregation (e.g., Assembly, Subordination, etc.) is sufficient for presentation to humans, and showing the multiplicities on the diagram produces needless clutter. A tool vendor could choose to set default multiplicity values in the models based on the specific Aggregation sub-Stereotype.

\[\begin{align*}
\text{aggregate} \\
\langle\langle\text{Aggregation}\rangle \\
\text{part of one type} & \quad \text{part of another type}
\end{align*}\]

*Figure 3-78  Notation for Shared, Non-Binary Aggregation*

---

17. This diagram notation, as well as notations for subtypes of Aggregation and for Symmetric Relationships, show – as an example! – two target types. Except for Reference relationships, there may be any strictly positive number of target types.
Figure 3-79  Notation for Composite, Non-Binary Aggregation

Note – At some abstraction level it may be unknown or unimportant whether the diamond is white or black, i.e., whether the Aggregation is hierarchical or not. In this case, the choice is to be less restrictive: the Aggregation is, by default, non-hierarchical (the diamond is white). The explicit specification of the <<Aggregation>> Stereotype may not be needed since the diamond takes care of that.

Observe also that in some cases the modeler does not want to make certain choices because such choices – at that particular specification stage – may be unimportant or irrelevant. This is an example of using abstraction to suppress irrelevant details.

Thus it may well be possible that the modeler will choose <<Aggregation>> without making any further decisions as to the specific subtype of this <<Aggregation>>, and therefore this Stereotype is not abstract.

At the same time, the invariant of <<Aggregation>> includes a substantial amount of important semantic information, specifically, information about property values of the aggregate determined by property values of its parts; this is a very important consideration in choosing an <<Aggregation>> as opposed to other relationships.

3.26.1.2 Stereotype: Assembly

Inheritance

Association
  Aggregation
  Assembly

18. This approach is quite intuitive and has a certain consistency with the notation used for depicting Generalization partitions (i.e. subtype hierarchies).
**Instantiation in a model**

Concrete

**Semantics**

An Assembly is an Aggregation for which the aggregate (whole) cannot exist without its parts.

**Tagged Values**

None

**Constraints**

**Constraints Expressed Generically**

*Invariant:* The existence of an aggregate instance implies the existence of at least one corresponding part instance.

**Formal Constraints Expressed in Terms of the UML Metamodel**

**English**

*Invariant:* The multiplicity of the part ends of the association must have a lower bound of at least 1.

**OCL**

\[
\text{inv Part Multiplicity:}\,
\text{let parts= self.connections->select (end | end.aggregation = \#none) in parts->forAll (multiplicity.range->forAll (lower >= 1))}
\]

**Note** – The sub-Stereotypes of Aggregation (Assembly, Subordination, etc.) essentially specify a set of multiplicity constraints. At first glance the UML-aware reader may conclude that these Stereotypes merely duplicate the ability to express multiplicity that UML already has and are therefore unnecessary. In order to understand the added value, one must consider non-binary Aggregations.

For example, the invariant of Assembly constrains the multiplicities on all of the part AssociationEnds in a non-binary Aggregation, and thus adds another level of validation that can be conducted as to whether a model is well formed. In addition, multiplicities in this context are realizations of the semantics specified in the appropriate invariants at a (somewhat) higher abstraction level preferable for human readers.

**Diagram Notation**

The notation for Aggregation is used (see Figure 3-78 and Figure 3-79), except that the Stereotype keyword is <<Assembly>>. Therefore the specific diagrams are not provided here.
3.26.1.3 Stereotype: Subordination

Inheritance
Association
  Aggregation
  Subordination

Instantiation in a model
Concrete

Semantics
A Subordination is an Aggregation for which the parts cannot exist without their aggregate (whole).

Tagged Values
None

Constraints

Constraints Expressed Generically
Invariant: The existence of a part instance implies the existence of at least one corresponding aggregate instance.

Formal Constraints Expressed in Terms of the UML Metamodel

English
Invariant: The multiplicity of the aggregate end of the association must have a lower bound of at least 1.

OCL

inv AggregateMultiplicity:
let aggregate = self.connections->select (end | end.aggregation <> #none) in aggregate.multiplicity.range ->forall (lower >= 1)

Diagram Notation
The notation for Aggregation is used (see Figure 3-78 and Figure 3-79), except that the Stereotype keyword is <<Subordination>>. Therefore the specific diagrams are not provided here.

3.26.1.4 Stereotype: Packet

Inheritance
Association
Aggregation
Packet

Instantiation in a model
Concrete

Semantics
A Packet is an Aggregation for which the parts can exist without their aggregate, and the aggregate can exist without its parts. This is the default for Aggregation.

Tagged Values
None

Constraints
No additional Constraints beyond those inherited from Aggregation.

Diagram Notation
The notation for Aggregation is used (see Figure 3-78 and Figure 3-79), except that the Stereotype keyword is <<Packet>>. Therefore the specific diagrams are not provided here.

3.26.1.5 Stereotype: List

Inheritance
Association
  Aggregation
    Assembly
      List
Association
  Aggregation
    Subordination
      List

Instantiation in a model
Concrete

Semantics
A List is an Aggregation for which the parts cannot exist without their aggregate, and the aggregate cannot exist without its parts. Thus, a List is a subtype of both Assembly and Subordination; both subtypings are incomplete.

Tagged Values
None
3

Constraints
No additional Constraints beyond those inherited from Assembly and Subordination.

Diagram Notation
The notation for Aggregation is used (see Figure 3-78 and Figure 3-79), except that the Stereotype keyword is <<Packet>>. Therefore the specific diagrams are not provided here.

3.26.1.6 Special Notes on Shared and Composite Aggregations
As mentioned above, any of the forms of Aggregation defined here can be used with either shared or composite aggregation (also known as weak and strong aggregation, respectively). Sometimes it is helpful to think of shared and composite aggregations as non-hierarchical and hierarchical aggregations, respectively.

In UML the aggregate in a composite aggregation is allowed to have multiplicity of either 1..1 or 0..1, although many modelers are under the misconception that composite aggregation implies a multiplicity of 1..1 for the aggregate.

A composite aggregation stereotyped as a <<Subordination>> constrains the aggregate’s multiplicity to 1..1. Similarly, in UML the aggregate in a shared aggregation is allowed to have multiplicity of either 1..* or 0..*. A shared aggregation stereotyped as a <<Subordination>> constrains the aggregate’s multiplicity to 1..*.

3.26.2 Reference Relationships

3.26.2.1 Stereotype: AbstractReference

Inheritance
Dependency
AbstractReference

Instantiation in a model
Abstract

Semantics
The property values of one participant – the maintained – are determined, in part, by the property values of the other participant – the referenced. The maintained and referenced participants are the client and supplier, respectively, in the UML Dependency relationship. AbstractReference is specialized into Reference and ReferenceForCreate, as shown below.

Tagged Values
None
Constraints

Constraints Expressed Generically

Invariant: The existence of a maintained instance implies that if a corresponding instance of the reference type exists, then some property values of the instance of the maintained element are determined by some property values of the corresponding instance of the referenced element.

Formal Constraints Expressed in Terms of the UML Metamodel

It is not possible to express the constraints formally in terms of the UML metamodel.19

Diagram Notation

Since AbstractReference is abstract, no notation is defined for it. However, notation is defined for its sub-Stereotypes.

3.26.2.2 Stereotype: Reference

Inheritance

Dependency
  Reference

Instantiation in a model

Concrete

Semantics

A Reference is the most common form of AbstractReference for which the property values of the maintained instance are determined, in part, by the current property values of the referenced instance.

Tagged Values

None

19. However, it is possible to define an implementation mapping. See notes in the sections on Reference and ReferenceForCreate below.
Constraints

Constraints Expressed Generically

Invariant: The property values of the maintained instance are determined, in part, by the current property values of the referenced instance. The property values of the client must be reviewed and possibly changed whenever any of the properties of the supplier changes.

Formal Constraints Expressed in Terms of the UML Metamodel

It is not possible to express the constraints formally in terms of the UML metamodel.

Diagram Notation

The notation is the standard UML Dependency notation with the <<Reference>> Stereotype, as shown in Figure 3-80. Note that <<Reference>> can be abbreviated as <<Ref>>.

![Figure 3-80 Notation for Reference](image)

3.26.2.3 Stereotype: ReferenceForCreate

Inheritance

Dependency
  AbstractReference

Instantiation in a model

Concrete
**Semantics**

A ReferenceForCreate is an AbstractReference for which the property values of the \textit{maintained} instance are determined, in part, by the property values of the \textit{referenced} instance at the time that the maintained instance is created. Once the maintained instance is created, its properties are not affected by changes to the referenced instance.

**Tagged Values**

None

**Constraints**

\textit{Constraints Expressed Generically}

The property values of the \textit{maintained} instance are determined, in part, by the property values of the \textit{referenced} instance at the time that the maintained instance is created. The properties of the referenced element must be examined whenever an instance of the maintained element is created.

\textit{Constraints Expressed in Terms of the UML Metamodel}

It is not possible to express the constraints formally in terms of the UML metamodel. The notation is standard UML Dependency notation with the \texttt{<<ReferenceForCreate>>} Stereotype, as shown in Figure 3-81.

![Figure 3-81 Notation for ReferenceForCreate](image-url)
3.27 Mapping the Relationships to Technical Platforms

This non-normative subsection addresses the mapping of the relationships defined in this document to technical platforms such as CORBA IDL, XML, Java, etc.

A mapping to a technical platform can use one of two basic approaches:

**Type 1.** It can describe how to transform a model to a set of declarations expressed in the native declarative language of the chosen technical platform. This kind of transformation targeted to the CORBA platform generates declarations expressed in CORBA IDL, i.e. CORBA interfaces, valuetypes, etc. If targeted to the Java platform, it generates declarative Java code, i.e. Java interfaces and abstract classes. If targeted to XML, it generates an XML DTD or XML Schema, both of which are essentially declarative code.

**Type 2.** It can describe how transform a model to another UML model expressed in terms of a UML profile targeted to the chosen technical platform, such as the UML Profile for CORBA\(^{20}\) or the UML Profile for EJB\(^{21}\). Such UML profiles support expression via UML of declarative semantics in terms of the concepts native to the chosen technical platform.

Within the scope of this mapping section, we refer to these two types of mappings as Type 1 and Type 2 mappings.

### 3.27.1 Aggregations

**3.27.1.1 Decomposing Non-Binary Aggregations**

Any Type 1 or Type 2 mapping algorithm that covers the transformation of UML 1.4 binary aggregation associations can be applied in a straightforward manner to the transformation of non-binary aggregations. Prior to executing the transformation, all non-binary aggregations should be decomposed into binary aggregations. The rules for decomposition are as follows:

- The participant classifier (i.e., the type) of the aggregate end of the non-binary aggregation becomes the participant classifier on the aggregate end of all of the binary aggregations resulting from the decomposition.
- The properties (such as name and multiplicity) of the aggregate end of each of the resulting binary aggregations are the same as the properties of the aggregate end of the non-binary aggregation. There is one exception to this rule:
- Typically the name of the aggregate end of each of the binary aggregations is the same as the name of the aggregate end of the non-binary aggregation, as illustrated by Figure 3-82. The exception case is where more than one of the

\(^{20}\) [UML-CORBA]  
\(^{21}\) [JSR-40]
aggregee ends of the non-binary aggregation have the same participant classifier, as in Figure 3-83, where Z is the participant classifier for two aggregee ends of the non-binary aggregation. In that case, there would be a name conflict if the aggregate end of both of the resulting non-binary aggregations had the same name (e.g. if both of the aggregate ends opposite Z in Figure 3-83 were named “a”). The rule for disambiguating the aggregate end names is to prepend the name with the name of the aggregee end. Thus in Figure 3-83, “z2” and “z” are prepended to the names of the respective aggregate ends of the binary aggregations.

- The participant classifier of the aggreggee ends of the non-binary aggregation become the respective participant classifiers of the aggreggee ends of the resulting binary aggregations.
- The properties of the aggreggee end of each of the resulting binary aggregations are the same as the properties of the corresponding aggreggee ends of the non-binary aggregation.

3.27.1.2 Ignoring Aggregation Sub(stereo)types

Type 1 and Type 2 mapping algorithms should ignore all of the specific aggregation stereotypes defined in this profile that modify the a binary or non-binary aggregation (Assembly, Subordination, List, and Packet). These specific stereotypes are merely constraints on the multiplicities of the association ends. Any mapping of standard UML 1.4 aggregation associations would have to have rules for how the transformation is affected by these multiplicities. The presence of the stereotypes does not mean that these multiplicities are missing. Therefore the multiplicities can drive the transformation and the stereotypes are redundant.

3.27.1.3 Leveraging General Mappings

With these rules in hand, well-defined mappings such as the MOF-IDL\(^{22}\), MOF-XML (i.e. XMI)\(^{23}\), and MOF-Java\(^{24}\) mappings can be readily applied to the kind of binary and non-binary aggregations associations supported by this relationship profile. Since these well-defined mappings specify how to transform MOF models, some slight adjustments are necessary to apply them to UML models. The adjustments are quite minor and are necessitated by the slight degree to which the MOF and UML are out of sync with each other, a misalignment that is slated to be fixed by the UML 2.0 Infrastructure RFP process.

22. [MOF 1.3]
23. [XMI 1.1]
24. [JSR-40]
As an alternative to using MOF technology mappings, UML technology mappings can be leveraged as well. There are currently no standardized UML technology mappings, but a number of tools have defined their own proprietary mappings. Again, by applying the rules for decomposing non-binary aggregations it is straightforward to leverage such mappings.

Figure 3-82  Association End Names Resulting from Decomposing a Non-Binary Aggregation (General Case)
3.27.2 Reference Relationships

Reference dependencies are not used to drive Type 1 or Type 2 transformations. Mapping algorithms ignore them, treating them essentially as documentation. References are most typically used in conceptual models that are not used as input for transformations.

*Figure 3-83*  Association End Names Resulting from Decomposing a Non-Binary Aggregation (Special Case)
3.28 Examples Using the UML Extensions

3.28.1 Example: List and Subordination

This example [15] (see Appendix A) demonstrates a fragment of an accounting specification in which it was essential to show and to distinguish between specific Stereotypes of Aggregation25.

A reconciliation in accounting compares one collection of accounts having a particular account representation with another collection of accounts having a different, but related, account representation. As a result of a reconciliation comparison, pair-offs and breaks are found.

Each pair-off results in two sets of account items. One set, drawn from one collection of accounts, corresponds (in accordance with “matching criteria” chosen by the user) to another set drawn from the other collection of accounts. (Although each account item is a part of exactly one account, the account items in the set that participates in a pair-off may be drawn from more than one account.) A pair-off happens because corresponding sets of account items were found, and:

- either these lists are representations of the same transaction and their (monetary values for) account items pair-off (match) within tolerance, or

- it is not important whether these sets are representations of the same transaction(s), but the sum of (monetary values for) account items in one representation is equal, within a specified tolerance, to the sum of (monetary values for) account items in the other representation.

Account items from either collection that do not participate in a pair-off represent breaks. Account items that are parts of breaks participate, together with the collections of accounts mentioned above, in subsequent reconciliation activities. A break will disappear as a result of a subsequent, possibly manual, pair-off. Figure 3-84 shows a fragment of this specification.)

25. If it were necessary to apply the currently existing UML 1.3 then some fragments of this specification would be shown using the (partial!) realization of these Stereotypes by means of multiplicities, and in some cases the problems would look very severe because of the need to show a non-binary aggregation. However, the excessive amount of multiplicities would overload the diagram, and its understanding by users would be much more difficult since the diagram would show the realization of a construct rather than the (abbreviation of the) construct itself.
Figure 3-84  Fragment of Reconciliation Specification

Figure 3-84 shows that AnAccountSet is an Assembly of AccountItems, so that in order for AnAccountSet to exist, its AccountItems have to exist. Further, AnAccountSet is specialized into OneAccountSet and AnotherAccountSet for reconciliation purposes, as described above.

Each AccountSet is drawn, when a reconciliation (attempt) is accomplished, from its AccountCollection, so that the AccountCollection has to exist first. And finally, a PairOffOrBreak is a List since it results in establishing a reconciled (or non-reconcilable) correspondence between OneAccountSet and AnotherAccountSet. Therefore all three participants of the Aggregation are essential for the existence of this Aggregation.
3.28.2 Example: Reference Relationships

This example demonstrates the semantics of property determination for information input and its syntactic and semantic validation. As this and other examples show, multiplicities are not the most important fragment of relationship semantics; specifically, the purpose of the specification shown here is to demonstrate relationships used for property determination.

Without the <<Reference>> Stereotype it would be necessary to use Notes in a class diagram or informal prose to represent the semantics. As shown in the class diagram below, the essential structure of the specification becomes clear only by means of the <<reference>> generic relationship Stereotype.

![Figure 3-85 <<Reference>> Stereotype Used To Show Structure of Specification](image-url)
Figure 3-85 shows a typical (and recommended!) approach to a common situation during information input and validation [11] (see Appendix A). The proposed values for the business entity are to be entered from a screen and checked for correctness. These screen-entered values by themselves do not determine the values of the ValidatedBusinessEntity. Rather, there are both syntax checks (for example, that the value is of the appropriate base type such as “integer”) and semantic checks (for example, that the value belongs to the set of permissible values such as “state name;” or that the customer that claims to be known is actually known).

Business rules are specified for the SyntaxCheck and for the SemanticValidation. Each business rule, as a maintained entity, has two reference relationships – pointing to the EntryWindowForABusinessEntity and to the InformationForValidation – since the properties of the business rule will be determined, in part, by the properties of two of its reference entities. Similarly, the ValidatedBusinessEntity has two reference relationships pointing to these two business rules since the properties of the ValidatedBusinessEntity will be determined, in part, by the properties of these rules.

Clearly, the specific property determination invariants will have to be provided explicitly in the specification of each of these reference relationships. The diagram indicates that these relationships exist and that such invariants are to be provided – otherwise the specification is incomplete. If these invariants are simple enough, then they may also be represented as Notes in the diagram.

Section I - Rationale

4.1 Introduction

The UML Profile for EDOC specification is designed to provide standard means, Business Function Object Patterns (BFOP), for expressing object models using UML package notation together with the mechanisms for applying patterns that are required to describe models.

Successful implementation of an enterprise computing system requires that the system operation to be directly related to the business processes it supports. Reusable standard models are required in order to build good object models for EDOC systems.

Standard models have Business Entities Objects, Business Processes Objects, Business Event Objects and Business Rules Objects of ECA. They also include a set of common and reusable patterns of relationship properties that occur in business modeling. BFOP is being developed to achieve this objective.

BFOP is a set of object patterns laid out in a hierarchical multi-layer structure, the Basic, Unit, Basic Model, Product (application systems), and Option layers.

Figure 4-1 on page 4-3 illustrates how “Sales/Purchase Pattern” is composed from “Sales Order & Purchase Order Pattern,” “Closing Pattern,” and so on. The UML parameterized collaboration mechanism is used to materialize the pattern integration.

One of the major benefits for using this multi-layered structure is that it enables reuse (inheritance) of the constraints that have been defined and encapsulated in patterns in the layers. It provides a normalized way to define constraints and is effective in maintaining consistency within the object model.

The proposed notion of Business Pattern Package (BP Package) defining a pattern and Business Pattern Binding (BP Binding) applying a pattern has the features of pattern inheritance and pattern composition. This capability is useful for expressing patterns that include the objects constructed by recursive component composition of ECA.
4.2 Pattern Principle

A pattern is something used to represent modeling know-how or techniques that help developers to maintain efficiency and consistency in products.

In the world of object modeling, many approaches to the use of patterns have been proposed, for example, “Design Pattern” proposed by E. Gamma et al [Gamma 95], “Analysis Patterns” proposed by M. Fowler [Fowler 97], or “Catalysis Approach” proposed by D. D’Souza [D’Souza 99]. In its use of patterns this submission focuses more on improving sharability and reusability of object models than on assisting modeling efforts by illustrating good modeling techniques.

To improve sharability and reusability of object models, patterns must support the following features:

- The model must offer predefined normative modeling constructs, not just modeling conventions and notations.
- Predefined modeling constructs should include the common atomic objects, such as, Date, Currency, Country-code, which can then be used without explanation.
- Common aggregated objects, such as Customer, Company, or Order, which represent business entities, also should be predefined as normative modeling constructs, using the normative atomic objects.
- Business concept, such as, Trade, Invoice, or Settlement, which are typically represented as relationship among objects, should be defined as aggregations of the common elementary aggregated objects or simple objects. They also have to be predefined as normative modeling constructs.

Figure 4-1 An Example of BFOP Pattern Hierarchy
• Those aggregations that can be predefined using more basic and elementary patterns as a base, may be defined as object patterns.

• Patterns can represent a business concept where they provide for aggregation of more elementary patterns. Therefore, the aggregation or composition mechanism is an essential element of patterns.

4.3 Notation for Patterns

Business rules that govern a business concept can be represented with a pattern with constraints encapsulated in it. Thus, the mechanism for constraint inheritance among patterns must be provided.

In this section, the concept and format of patterns are discussed from the viewpoint of pattern notation, relationships among patterns and pattern types and their instances.

We considered that there are three basic forms on expressing patterns. First, the simple pattern which is a pattern consisting of minimal elements needed to form a pattern. Second, the inherited pattern which is a pattern defined by inheriting from another pattern. And the third is the composite pattern which is a pattern defined as a result of combining more than two patterns. The composite pattern concept is an extension of the inherited pattern. Using the above three basic pattern forms as the base, we propose the following notations for expressing patterns and their metamodel.

It is important to consider the issue of type and its instantiation from the metamodel viewpoint. A pattern is a set of types that can be instantiated to create object models. A pattern for a set of object models is created by identifying and defining the common types among those object models, using a metamodel such as in the ECA profiles. Identifying and specifying many reusable business object patterns is useful for quick and high quality model development that can be attained by selecting appropriate patterns among various ones to use in the project as a template.

The instantiation of a composite pattern in a hierarchical structure becomes possible by resolving pattern inheritance and collaboration by "unfolding". When a composite pattern is granular enough to include implementation details, and it is possible to use it to describe a component concept such as CCA, each pattern package can be implemented with real components instead of unfolding it into a component pattern. In short, the proposed pattern concept and mechanism can be applied to the components based development that is required in EDOC.
**Figure 4-2** Defining the “Composition” Pattern

**Figure 4-3** Applying the “Composition” Pattern
4.4 Simple Pattern

A simple pattern consists of minimal elements and does not involve another pattern. In BFOP, type (i.e., an abstract class) and relationship among types are significant elements for specifying the static structure of a simple pattern. In addition to the static structure, operations are defined to characterize the pattern's behaviors. Constraints for the operation can be specified as the pre/post conditions described in OCL. Figure 4-5 illustrates the notation for a simple pattern.

4.5 Pattern Inheritance

The pattern inheritance mechanism is provided to describe a pattern that is defined in conjunction with another already existing pattern. The names of types and attributes in the inherited pattern can be renamed as appropriate for the inheriting pattern. This provides the way to build various patterns for specific usage.
For instance, the pattern `<header>-<detail>` can be used to generate many patterns that share the common characteristics of the header-detail. Typically, patterns inherited from the `<header>-<detail>` need stricter constraints than the original pattern. If the pattern `<A>-<B>` is created from the pattern `<A>-<B>`, the types A and B are replaced with subtype A' and B' respectively. Figure 4-6 shows the notation and mechanism of the inherited pattern.

![Figure 4-6 The Format of Pattern Inheritance](image)

### 4.6 Pattern Composition

The third form of pattern, composite pattern, provides a way to build more complex patterns. When combining two patterns to describe a composite pattern, a new type (i.e., logical class) is created which shares the common characteristics of the original patterns. The new combining type is expressed using the parameterized collaboration in UML 1.4. The pattern composition is useful for building hierarchical structure of patterns. Figure 4-7 is a simple diagram illustrating the notation of composite pattern.
4.7 Summary of Pattern Formats

The pattern formats described above can be explained using package diagram in UML notation as in Figure 4-8.

4.8 Applying Patterns

The upper diagrams illustrate how the “Organization Pattern” is composed from “Employee Assignment Pattern” and “Organization Structure Pattern” in the BFOP hierarchy structure. The UML parameterized collaboration mechanism is used to
materialize the pattern integration. The lower diagrams of Figure 4-9 show the steps of unfolding. The right and down arrows show the generated “Organization (Subsystem).”

Figure 4-9  An Example of BFOP Structure and Unfolding
Section II - Patterns Metamodel

Figure 4-10 depicts the elements to be considered; those that are part of this profile specification are highlighted. This metamodel is organized with three main model elements to describe a Business Pattern: Business Pattern Name, Business Pattern Package and Business Pattern Binding. Business Pattern Names are to identify patterns defined with Business Pattern Packages and also are used to invoke patterns with those pattern names.

Figure 4-10  Metamodel for Business Pattern Package
4.9  EDOC::Pattern Package

4.9.1  Business Pattern Name

**Semantics**
Business Pattern Name is the name of business patterns defined by Business Pattern Package.

**UML base element(s) in the Profile**
Class

**Fully Scoped name**
EDOC::Pattern::Business Pattern Name

**Owned by**
Package

**Properties**

*Business Pattern Name*
Business Pattern Name is the name of pattern defined in Business Pattern Package.

**Related elements**

*Namespace*
Business Pattern Name inherits from Namespace and adds the Business Pattern Name of Business Pattern Package.

*Business Pattern Package*
Business Pattern Package specializes Business Pattern Name for defining Business Pattern Package associating Business Pattern Name.

*Business Pattern Binding*
Business Pattern Binding specializes Business Pattern Name for invoking Business Pattern Package with associated Business Pattern Name.

**Constraints**
None
4.9.2 Business Pattern Package

Semantics
Business Pattern Package is used to specify patterns and handle them as design elements.

UML base element(s) in the Profile
class

Fully Scoped name
EDOC::Pattern::Business Pattern Package

Owned by
Package

Properties
N/A

Related elements
Business Pattern Name
Business Pattern Package inherits from Business Pattern Name and adds elements for defining a pattern.

Package
Business Pattern Package inherits from package and adds elements for defining a pattern.

Template Parameter
Template Parameter represents formal parameters of defined pattern, which are class names to be replaced with actual class names at unfolding pattern.

Constraint
Constraint declares the semantics of defined pattern. A Business Pattern Package can be specified more precisely.

Operation
Operation is the set of method definitions and extends the functions of patterns. A Business Pattern Package can be handled like a component or a class.
Owns
Business Pattern Package owns a template in a parameterized collaboration diagram with constraints and operations.

Constraints
None

4.9.3 Business Pattern Binding
Business Pattern Binding indicates applying patterns and also represents a parameterized collaboration.

UML base element(s) in the Profile
Collaboration

Fully Scoped name
EDOC::Pattern::Business Pattern Binding

Owned by
Package

Properties
N/A

Related elements

Business Pattern Name
Business Pattern Binding inherits from Business Pattern Name and add elements for invoking a pattern.

Collaboration
Business Pattern Binding inherits from Collaboration and adds elements for invoking a pattern.

Template Parameter
Template Parameter represents to replace the elements of patterns such as class names or attributes when patterns are unfolded in another pattern or class diagram.

Replaces with renaming
The element names such as class name, attribute name or method name used in patterns are replaced when patterns are unfolded.
4

Constraints
None

Section III - UML Profile

4.10 Table mapping concepts to profile elements

Table 4-1 provides a mapping of metamodel elements to UML profile elements.

4.11 Introduction

Figure 4-11 illustrates the extensions required for the pattern model and the relationships of these extensions to elements in UML 1.4. The extensions shown in this diagram are discussed in the paragraphs that follow.

The BP Package is a stereotype which inherits BP Name and Package for defining a new pattern, the BP Binding is a stereotype which inherits BP Name and Collaboration for pattern invocation with renaming, and the BP Name is a stereotype which inherits Namespace for identifying and sharing a pattern name between a BP Package’s stuff and a BP Binding’s stuff.

Figure 4-11  Patterns <<profile>> Package
4.12 Pattern Package

4.12.1 BP Name

Inheritance
This stereotype has the following inheritances:
Package (from UMLCore)
  BP Package

Instantiation in a model
Abstract

Semantics
The BP Name is a stereotype that inherits Namespace for identifying and sharing a pattern name between a BP Package’s stuff and a BP Binding’s stuff.

Tagged Values
N/A

Constraints
N/A

Diagram Notation
N/A

4.12.2 BP Package

Inheritance
This stereotype has the following inheritances:
Package (from UMLCore)
  BP Package
  BP Name
    BP Package

Instantiation in a model
Concrete
**Semantics**

The BP Package is a stereotype that inherits BP Name and Package for defining a new pattern. A pattern definition consists of a BP Name and a collaboration diagram as a pattern body. A collaboration diagram may have some BP binding which invoke patterns with renaming. The notion of renaming is not included in collaboration of UML 1.4. However, the collaboration diagram created by unfolding pattern is a collaboration diagram in UML 1.4.

One of the major benefits for using this multi-layered structure is that it enables reuse (inheritance) of the constraints which have been defined and encapsulated in patterns in the layers. It provides a normalized way to define constraints and is effective in maintaining consistency within the object model.

The Operations of the BP Package are provided to treat the BP Package as a class or component. It can be used to draw a pattern of component relations and refinement relations between lower and upper of abstraction model level.

**Tagged Values**

N/A

**Constraints**

N/A

**Diagram Notation**

![Diagram Notation for Business Pattern Package](image)

*Figure 4-12 Notation for Business Pattern Package*
4.12.3 BP Binding

Inheritance

This stereotype has the following inheritances:

Package (from UMLCore)
  BP Binding
BP Name
  BP Package

Instantiation in a model

Concrete

Semantics

The BP Binding is a stereotype that inherits BP Name and Collaboration for pattern invocation with renaming.

The renaming for model elements of pattern body may be allowed in pattern invocation.

Here, instead of UML’s graphical notation, lets use symbolic expressions for explaining the meaning of pattern framework concerning renaming as follows.

Formal Parameter ::=<…>
Pattern definition::
  defpattern “pattern name” = “pattern body”
Pattern invocation ::
  “pattern name” ( “Actual parameter List”) [“Renaming List”]
Renaming List::
  [“Name”/”New Name”, ...,”Name”/”New Name”]

Example of pattern definition::

  defpattern A = <a > + <b> + c + d
  defpattern B = A(a1,b1)[c/c1] + e + f
  defpattern C = A(<a>, b2)

Example of pattern invocation and unfolded result:

  B( ) ( a1 + b1 + c1 + d + e + f
  B( )[c1/c2, e/e1] ( a1 + b1 + c2 + d + e1 + f
  C(a3) ( a3 + b2 + c + d

Here, the symbol “a”, “b”, “c”... is supposed to be a model element such a class name, attribute name and so no. The symbol “+” is supposed to be a model element like an association. The pattern A has two parameters “<a>” and “<b>”. Also, it has two model elements “c” and “d”. The “c” is renamed into “c1” in the pattern B. In this way, more general name like “c” is used in the pattern definition, but more specific name like “c1” is preferable in a concrete model.
**Tagged Values**

N/A

**Constraints**

If a corresponding actual parameter is not specified on BP Binding, formal parameter is used as a default element.

**Diagram Notation**

Section I - The EJB and Java Metamodels

5.1 Introduction

This section describes the Enterprise JavaBeans © metamodel abstracted for the purpose of design and deployment of application components to the Enterprise JavaBeans architecture. This metamodel describes the EJB 1.1 specification,
specifically the content of the “Public Release” version of the 1.1 specification. The metamodel is included to demonstrate the generality of the proposed analysis profile by showing that it can be mapped to more than one implementation architecture. The submitters believe this generality should be provided to maximize the utility of the profile.

The metamodel is intended to define sufficient structure to support the EJB development life cycle, i.e., the creation, assembly and deployment of Enterprise JavaBeans. As the Java language is the foundation to the Enterprise JavaBeans architecture, a Java metamodel has been developed as a foundation to the Enterprise JavaBeans metamodel. The intent of the Java metamodel is to capture sufficient detail to support the Enterprise JavaBeans metamodel. It is not a complete metamodel of the Java language. The Java metamodel describes the Java language specification used by EJB 1.1, i.e., Java language specification version 1.3.

The following pages will describe the two metamodels. Each metamodel is presented as a series of class diagrams. Each class diagram is followed by a description of the important features of the diagram. Each metamodel element can also be mapped to a profile representation using the patterns described in the UML Profile for MOF that is included in this document. As the metamodel is completed with the constraints spelled out in the Enterprise JavaBeans architecture, those can also be projected into the profile. The submitters intend the metamodel to be used as input for the UML Profile for EJB now in public draft within the Java Community Process under JSR-000026 (see http://jcp.org/jsr/detail/26.jsp) through such a mapping.

### 5.2 The Java Metamodel

The Java metamodel is described using the following 5 diagrams:

- Figure 5-1 on page 5-3, Class Contents describes Java Classes/Interfaces/Exceptions.
- Figure 5-2 on page 5-8, Polymorphism describes Java polymorphism.
- Figure 5-3 on page 5-9, JavaType describes how Java typed elements are related to their types.
- Figure 5-5 on page 5-11, Data Types describes the basic Java data types.
- Figure 5-6 on page 5-12, Names factors the name attribute into a superclass.
5.2.1 Class Contents

5.2.1.1 JavaPackage

Semantics
A Java package, as defined in the Java Language Specification.

Fully Scoped name
EDOC::Java::JavaPackage

Owned by
Package
5.2.1.2 JavaClass

Semantics
A Java class, as defined in the Java Language Specification.

Fully Scoped name
EDOC::Java::JavaClass

Owned by
JavaPackage

Properties
isPublic
Boolean value indicating whether the class is public.

isAbstract
Boolean value indicating whether the class is abstract.

IsFinal
Boolean value indicating whether the class is final.

Related elements
JavaPackage
The Java package the class is in.

JavaClass
Declared/Declaring classes.

Field
The fields in the class.
Method
The methods on the class.
The methods that throw this exception.

JavaParameter
The parameter type.

ArrayType
Subclasses JavaClass, adding array dimensions.
The type of the components in the array.

Constraints
N/A

5.2.1.3 Field

Semantics
A Java field, as defined in the Java Language Specification.

Fully Scoped name
EDOC::Java::Field

Owned by
JavaClass

Properties

isFinal
Boolean value indicating whether the field is final.

IsStatic
Boolean value indicating whether the field is static.

Related elements
JavaClass
The class containing the field.

Constraints
N/A
5.2.1.4 Method

**Semantics**
A Java method, as defined in the Java Language Specification.

**Fully Scoped name**
EDOC::Java::Method

**Owned by**
JavaClass

**Properties**

- `isAbstract`
  Boolean value indicating whether the method is abstract.

- `isNative`
  Boolean value indicating whether the method is native.

- `isSynchronized`
  Boolean value indicating whether the method is synchronized.

- `isFinal`
  Boolean value indicating whether the method is final.

- `IsConstructor`
  Boolean value indicating whether the method is a constructor.

- `IsStatic`
  Boolean value indicating whether the method is static.

**Related Elements**

- `JavaClass`
  The class the method belongs to.
  The exceptions the method throws.

- `JavaParameter`
  The input and return parameters on the method.
5.2.1.5 JavaParameter

**Semantics**
A Java parameter, as defined in the Java Language Specification.

**Fully Scoped name**
EDOC::Java::Parameter

**Owned by**
Method

**Properties**

isFinal
Boolean value indicating whether the parameter is final.

**Related elements**

Method
The method the parameter is an input or return parameter for.

**Constraints**
N/A

5.2.1.6 ArrayType

**Semantics**
A Java array type, as defined in the Java Language Specification.

**Fully Scoped name**
EDOC::Java:ArrayType

**Owned by**
Package

**Properties**

arrayDimensions
Integer value giving the dimensions of the array type.
5

Related elements

JavaClass

Subclasses JavaClass and adds array dimensions.

ArrayType uses JavaClass to identify the type of its components.

Constraints

N/A

5.2.2 Polymorphism

Figure 5-2  Polymorphism

5.2.2.1 JavaClass

See Section 5.2.3.1, “JavaType,” on page 5-10 for Semantics, Fully Scoped name, Owned by, and Properties.

Related elements

JavaClass

The relationships in Figure 5-2 represent:

Super/sub-classing of classes and interfaces

The relationship between interfaces and implementing classes.

The JavaClass on the left represents an implementing class. The one on the right represents an interface.

Constraints

N/A
5.2.3 JavaType

Field, JavaParameter, ArrayType, and JavaClass are described in TypedElement.

**Semantics**
Abstract class that identifies subclasses as having a type as part of their definition.

**Fully Scoped name**
EDOC::Java::TypedElement

**Owned by**
Package

**Properties**

**Related elements**

*JavaType*
The associated type.

*Field, JavaParameter, ArrayType*
Concrete subclasses.

**Constraints**
N/A
5.2.3.1 JavaType

**Semantics**
Abstract class whose subclasses are the Java types.

**Fully Scoped name**
EDOC::Java::JavaType

**Owned by**
Package

**Properties**

**Related elements**

*JavaType*
The elements that are of this type.

*ArrayType, JavaClass, JavaDataType*
Concrete subclasses.

**Constraints**
N/A

5.2.4 TypeDescriptor

![Diagram of TypeDescriptor](image)

*Figure 5-4  TypeDescriptor*
5.2.4.1 **TDLangClassifier**

TDLangElement is a class in the Common Application Metamodel, which is part of the Enterprise Application Integration submission due to finalize in August. It is used in the model to tie TypedElements (via TDLangElement) into the data typing and type composition structure that this metamodel provides, as well as to JavaTypes.

5.2.4.2 **TDLangElement**

TDLangElement, also a class in the Common Application Metamodel, provides the linkage to TDLangClassifiers.

5.2.5 **Data Types**

![Data Types Diagram]

*Figure 5-5  Data Types*

This diagram describes the primitive data types and other types used within this metamodel, and is included for completeness.
5.2.6 Names

This diagram shows the factoring of the name attribute into an abstract superclass called NamedElement. It is included for completeness.

5.3 The Enterprise JavaBeans Metamodel

This metamodel is dependent on the Java metamodel described above. It captures the concepts that will be used to design an Enterprise JavaBean-based application down to the Java implementation classes.
5.3.1 Main

Session and Entity are the two main object types for components implemented using the Enterprise JavaBeans architecture. Entity and Session derive from an abstract parent class, EnterpriseBean.

5.3.1.1 EJBJar

Semantics
The EJBJar element is the root element of the EJB deployment descriptor.

Fully Scoped name
EDOC::EJB::EJBJar

Owned by
Package

Properties

description
The description element is used by the ejb-jar file producer to provide text describing the parent element. The description element should include any information that the ejb-jar file producer wants to provide to the consumer of the ejb-jar file (i.e. to the Deployer). Typically, the tools used by the ejb-jar file consumer will display the description when processing the parent element.

displayName
The display-name element contains a short name that is intended to be display by tools. Example: <display-name>Employee Self Service</display-name>.

SmallIcon
Optional small icon file name.

LargeIcon
Optional small icon file name.

EjbClientJar
Optional name of an ejb-client-jar file for the ejb-jar.

Related elements

Assembly
Assembly descriptor.

EnterpriseBean
Included EnterpriseBeans.

Constraints
N/A

5.3.1.2 Assembly

Semantics
The assembly-descriptor element contains application-assembly information. The application-assembly information consists of the following parts: the definition of security roles, the definition of method permissions, and the definition of transaction attributes for enterprise beans with container-managed transaction demarcation. All the parts are optional in the sense that they are omitted if the lists represented by them are empty. Providing an assembly-descriptor in the deployment descriptor is optional for the ejb-jar file producer.
5.3.1.3 EnterpriseBean

**Semantics**
EnterpriseBean is a class. It can have attributes, operations, and associations. These are actually derived/filtered from its implementation classes and interfaces. For mapping and browsing purposes, though, you would like the EnterpriseBean to appear as a class.

In this light, even Session Beans can have associations and properties implemented by their bean. For example, it would be meaningful to describe associations from a Session to the Entities that it uses to perform its work.

**Fully Scoped name**
EDOC::EJB::EnterpriseBean

**Owned by**
EJBJar

**Properties**

**Description**
The description element is used by the ejb-jar file producer to provide text describing the parent element. The description element should include any information that the ejb-jar file producer wants to provide to the consumer of the ejb-jar file (i.e., to the Deployer). Typically, the tools used by the ejb-jar file consumer will display the description when processing the parent element.
displayName
The display-name element contains a short name that is intended to be display by tools.

SmallIcon
Optional small icon file name.

LargeIcon
Optional small icon file name.

Related elements

EJBJar
Identifies the deployment descriptor it belongs to.

Session, Entity
The concrete subclasses of EnterpriseBean

Constraints
N/A

5.3.1.4 Session

Semantics
A transient object which provides more behavior than state. It maps to session bean in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::Session

Owned by
Package

Properties

transactionType
The transaction-type element specifies an enterprise bean's transaction management type.

sessionType
Whether the session bean is stateful or stateless.
5.3.1.5 Entity

Semantics
A persistent object which is more state-oriented than behavior-oriented. It maps to an entity bean in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::Entity

Owned by
Package

Properties
isReentrant
Boolean value indicating whether the entity bean is reentrant.

Related elements
EnterpriseBean
Abstract superclass.

Constraints
N/A
5.3.2 EJB

This diagram shows how EnterpriseBean is associated with objects that enable binding the deployed Enterprise Bean into the runtime environment and managing access to the bean.

5.3.2.1 EnterpriseBean

Semantics, Fully Scoped name, Owned by, and Properties are described in Section 5.3.1.3, “EnterpriseBean,” on page 5-15.

Related elements

SecurityRoleRef
Security role references by the enterprise bean.

EJBRef
References to the homes of other enterprise beans using “logical” names.

ResourceRef
References to external resources.
EnvEntry
Environment entries access by the enterprise bean.

Constraint
N/A

5.3.2.2 SecurityRoleRef

Semantics
Security role references by an enterprise bean

Fully Scoped name
EDOC::EJB::SecurityRoleRef

Owned by
EnterpriseBean

Properties

name
Name of the security role reference.

Description
Optional description text.

link
Used to link a security role reference to a defined security role. link must contain the name of a defined security role.

Related elements

EnterpriseBean
Enterprise bean that contains the reference.

Constraints
N/A

5.3.2.3 EJBRef

Semantics
The declaration of a reference to an enterprise bean’s home.
Fully Scoped name
EDOC::EJB::EJBRef

Owned by
EnterpriseBean

Properties

name
Name of the reference.

type
The expected type of the referenced enterprise bean.

home
The fully-qualified name of the enterprise bean’s home interface.

remote
The fully-qualified name of the enterprise bean’s remote interface.

link
Links an EJB reference to a target enterprise bean.

Description
Optional description text.

Related elements

EnterpriseBean
Enterprise bean that contains the reference.

Constraints
N/A

5.3.2.4 ResourceRef

Semantics
Declaration of an enterprise bean’s reference to an external resource.

Fully Scoped name
EDOC::EJB::ResourceRef
**Owned by**
EnterpriseBean

**Properties**

*Description*
Optional description text.

*Name*
Name of the environment entry used in the enterprise bean.

*type*
Type of the resource manager connection factory that the enterprise bean expects.

*auth*
Specifies whether the enterprise bean signs on programmatically to the resource manager, or whether the Container will sign on to the resource manager on behalf of the bean.

*link*
Link to a resource manager connection factory that exists in the operational environment.

**Related elements**

*EnterpriseBean*
Enterprise bean that contains the reference.

**Constraints**

5.3.2.5 *EnvEntry*

**Semantics**
Declaration of an environment entry for an enterprise bean.

**Fully Scoped name**
EDOC::EJB::EnvEntry

**Owned by**
EnterpriseBean
Properties

name
Name of the environment entry.

Description
Optional description text.

value
Value of the environment entry.

Type
Expected type of the environment entry’s value

Related elements

EnterpriseBean
Enterprise bean that contains the reference.

Constraints

N/A
5.3.3 Entity Bean

Figure 5-9 Entity Bean

Because Entities are persistent and state-oriented, they have additional associations compared to Sessions. This diagram shows how an Entity is associated with the Java fields which are its persistent and key fields. A ContainerManagedEntity’s persistent fields are a subset of the fields of its implementing EJB class. (ContainerManagedEntity is reified specifically to support this association.) The relationship of key fields is more complex, but when there is a complex key the key fields are a subset of the EJB class fields. These fields then correspond by name to fields of the Entity’s Primary Key Class.

Entity is described in Section 5.3.1.5, “Entity,” on page 5-17. Field is described in Section 5.2.1.3, “Field,” on page 5-5.

5.3.3.1 ContainerManagedEntity

Semantics

An Entity which delegates responsibility for persistence to the EJB container. Maps to an Entity Bean with Container-managed Persistence in the Enterprise.

Fully Scoped name

EDOC::EJB::ContainerManagedEntity
5

Owned by
Package

Properties

Related elements

Entity
ContainerManagedEntity adds the relationships shown in the diagram to it’s superclass Entity.

CMPAttribute
The key and persistent attributes of the Container-managed entity.

Field
The key and persistent Java fields of the Container-managed entity, derived from its CMPAttributes.

Constraints
N/A

5.3.4 Assembly

Figure 5-10  Assembly
When the components of an Enterprise JavaBean application are ready to be used, the assembly step adds permission and transaction structure to the components based on their usage in the application. Roles are authorized to methods based on the application’s needs. (AllMethodPermission captures the case where a role is authorized to all the methods of a class without having to enumerate those methods.) Based on the flow of control and the units of work defined in an application, the transaction requirements of methods can be declared. The method permissions and method transaction declarations are bundled into an Assembly Descriptor that is then realized in the deployed application artifacts.

5.3.4.1 AssemblyDescriptor
Semantics, Properties, Related elements map to the assembly-descriptor element in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::AssemblyDescriptor

Owned by
Package

5.3.4.2 SecurityRole
Semantics, Properties, Related elements map to the security-role element in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::SecurityRole

Owned by
AssemblyDescriptor

5.3.4.3 MethodElement
Semantics, Properties, Related elements map to the method element in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::MethodPermission

Owned by
MethodTransaction
5.3.4.4 MethodPermission

Semantics, Properties, Related elements map to the method-permission element in the Enterprise JavaBean specification.

*Fully Scoped name*

5.3.5 EJB Implementation

*Figure 5-11  EJB Implementation*
While users may think of an Enterprise Java Bean at the level of Entity and Session, the implementation of one of these constructs is actually a complex collaboration among several Java classes and interfaces. The metamodel defines associations which relate the more abstract Enterprise Bean constructs to the more concrete implementation types. When modeling an application, users should work with the home and remote interfaces exposed by the abstract constructs for interactions external to the bean, and with the implementation class for interactions internal to the bean. This dichotomy is necessary because of the differences between the remote and local interfaces to the bean required by the EJB architecture. The home and remote interfaces are remote, and contain methods inherited from the predefined interfaces EJBHome and EJBObject, respectively, that are not visible to the EJBBBeanClass. The signatures of the methods defined by the EJBBBeanClass are similar but not identical to the signatures of the methods defined by the home and remote interfaces. In addition, the EJBBBeanClass contains methods that are seen only by the container. These are inherited from the predefined EntityBean or SessionBean interface, depending on the type of the bean.

RemoteInterface is included here to denote that there is a kind of remote interface which is more generic than the EJB usage, but which has a known meaning and applicability in other domains, such as RMI or CORBA modeling.

5.3.5.1 EJBMethodCategory

Semantics

EJBMethodCategoryJava defines a mechanism which allows the modeler to group EJB-specific method types such as create methods, finder methods, remote methods, and home methods.

Fully Scoped name

EDOC::EJB::EJBMethodCategory

Owned by

Package

Properties

Related elements

Constraints

5.3.5.2 EnterpriseBean

EnterpriseBean is described in Section 5.3.1.3, “EnterpriseBean,” on page 5-15.
Related elements

JavaClass

The EjbClass relationship maps to the ejb-class element of the Enterprise JavaBean specification.

The remoteInterface relationship points to a Java interface that represents the remotely visible interface to an Enterprise Bean. Maps to the remote element in the Enterprise JavaBean specification.

The homeInterface relationship points to a Java interface which includes the factory and finder behavior of an Enterprise Bean. Maps to the home element in the Enterprise JavaBean specification.

5.3.5.3 Entity

Entity is described in Section 5.3.1.5, “Entity,” on page 5-17.

Related elements

JavaClass

The primaryKey points to a Java class which implements the key of the Enterprise Bean. Maps to an Entity’ primary key class in the Enterprise JavaBean specification.

5.3.6 References to Resources

The EjbRef is used for the declaration of a reference to an enterprise bean’s home. The declaration consists of an optional description; the EJB reference name used in the code of the referencing application client; the expected type of the referenced resource.

Figure 5-12 References to Resources

The EjbRef delegates its duplicate properties to the EnterpriseBean if it is linked to one.
enterprise bean; the expected home and remote interfaces of the referenced enterprise bean; and an optional ejb link information. The optional link is used to specify the referenced enterprise bean. The resource-ref element contains a declaration of the enterprise bean’s reference to an external resource. It consists of an optional description, the resource factory reference name, the indication of the resource factory type expected by the enterprise bean, and the type of authentication (bean or container). EnvEntry contains the declaration of an enterprise bean’s entries. The declaration consists of an optional description, the name of the environment entry, and an optional value.

5.3.6.1 SecurityRole

Semantics, Properties, Related elements map to the security-role element in the Enterprise JavaBean specification.

Fully Scoped name
EDOC::EJB::SecurityRole

Owned by
Package

5.3.6.2 J2EEResourceFactory

Semantics
A resource manager connection factory that exists in the operational environment.

Fully Scoped name
EDOC::EJB::J2EEResourceFactory

Owned by
Package

Properties

Related elements

ResourceRef
A resource reference bound to this actual resource factory configured in the target operational environment.
5.3.7 Data Types

This diagram describes the types used within this metamodel, and is included for completeness.
5.4 UML Profile

Each metamodel element can be mapped to a profile representation using the patterns described in the UML Profile for MOF (see Chapter 6). As the metamodel is completed with the constraints spelled out in the Enterprise JavaBeans architecture, those can also be projected into the profile. The submitters intend to align the metamodel with the UML Profile for EJB now in public draft within the Java Community Process under JSR-000026 (see http://jcp.org/jsr/detail/26.jsp) through such a mapping.

5.4.1 Java Profile

The convention used in this profile is that the classes from the Java metamodel are expressed as stereotypes in a Java model for use primarily in UML class diagrams. The attributes of the Java metamodel classes are tags to be applied on elements bearing the class stereotypes. The tag names are qualified by the stereotype they are applied with, since it is possible for a UML element to bear more than one stereotype.

The UML name of the element serves as the Java name unless the NamedElement.name tag is applied to override the name with a Java-specific name. This can be useful in cases where the UML name is not a valid Java name.

5.4.2 EJB Profile

This is provided by the UML Profile for EJB now in public draft within the Java Community Process under JSR-000026 (see http://jcp.org/jsr/detail/26.jsp).

Section II - Flow Composition Model

5.5 Introduction

The FCM is a Flow Composition Model (FCM) that can describe the interactions and flows of information between application components in a way that:

- Enables complex actions to be broken down into simple 'flow components' or, alternatively, enables simple entities to be composed into higher level 'flow models'.
- Can be deployed into a variety of runtime environments; in other words, the model treats its components as functional entities which are independent of any specific attributes of a particular deployment, whether that be a workflow, messaging service, etc.

Business applications are commonly made up of interrelated programs. These often run in multiple and different environments. The problem is: how to enable these disparate entities (which may not be directly connected nor running concurrently) to communicate with one another. It can be addressed through the concept of 'messaging' using, for example, MQSeries products. This method of Application Integration enables two (or several) programs to communicate in a relatively simple, static way. The programs, while isolated from each other in a 'time-independent' (asynchronous) fashion, mostly still need to know how to 'speak' to each other.

Each program needs to understand the other's message format; they need to speak the same 'language'. But with a little more sophistication, this need can be removed. A scenario can be created, usually known as Enterprise Application Integration (EAI), whereby messages are transformed into different formats so that programs need know nothing about the eventual recipient of a message. The added sophistication is a mediator between the programs provided by a message 'repository' and a message 'broker' to enable such transforms. Of course, there are other capabilities in brokers beyond transformation but this is probably the most important function.

As the applications become more isolated, the idea of 'routing' can be introduced. Now, another application can observe the content being shared through the broker and choose to modify the information flow. The process handling the information may be relatively long lived - typically the case where human intervention is involved. Also, the information being processed may be stateful (in other words, it persists beyond the scope of the process handling it). Workflow applications provide this sort of functionality and introduces the facility of 'multi-step sequencing'. By using various connectors, these different technologies can, and often are, used together.
The Flow Composition Model is a metamodel for composing complex flows based on invoking operations on components. It is a low-level metamodel focused on the middleware machinery for executing message flows. Higher levels of abstraction can be built upon the FCM for integrating a whole range of technologies and runtime environments:

- Messaging and Message Brokering provide for transformation and routing of information.
- Workflows provide application structuring and resource co-ordination.
- Connectors provide inter-operability with existing applications.
- Application Servers, Business Components, Databases and all the other programs which the flow model is there to drive but which, strictly speaking, are not actually part of the model.

Section 5.9, “Example,” on page 5-42 provides an example to illustrate the use of FCM.

### 5.6 FCMCore Package

The FCMCore package is described using two diagrams:

- Figure 5-14 – Main diagram gives an overall view of the classes required to define flow compositions.
- Figure 5-15 on page 5-34 – FCMComponent diagram provides more detail about FCMComponents, including how they can be used for hierarchical composition.

![Figure 5-14 FCMCore Package, Main Diagram](image-url)
5.6.1 FCMComposition

An FCMComposition defines the following:

- A set of FCMComponents that define the objects of the FCMComposition.
- A set of FCMNodes and FCMConnections that together define the implementations of the behaviors of the FCMComposition.
- A set of objects that define the public interface that can be derived from the FCMComposition. Specifically, the FCMSources and FCMSinks of an FCMComposition define the external operations that are derived from the FCMComposition.

An FCMComposition can be thought of as being analogous to the definition of the implementation of a Java or C++ class, in the sense that it defines interface, state and behaviors.

5.6.2 FCMComponent

The purpose of FCMComponents is to define the objects that hold the state of the FCMComposition, and which provide primitive behaviors that can be invoked within the implementations of behaviors defined by the FCMComposition.
5.6.3 FCMNode

An FCMNode represents a fragment of flow logic. It can be thought of as being analogous to a statement or contiguous sequence of statements in a programming language. FCMNodes are used to define the implementations of behaviors of the FCMComposition. FCMNodes are connected together in a graph using FCMConnections to build up more complex behaviors of the FCMComposition.

FCMNodes are represented as “nodes” or icons in flow diagrams.

5.6.4 FCMConnection

An FCMConnection is an object that specifies a relationship between two FCMNodes. Examples of FCMConnections are FCMControlLinks and FCMDataLinks (see the FCM Package, FCMConnections diagram). FCMConnections provide directed links between FCMNodes in a graph to specify more complex behaviors. The number and type of FCMConnections is extensible – the Flow Composition Model puts no constraints on this.

FCMConnections are represented in flow diagrams as lines that connect the icons representing FCMNodes.

5.6.5 FCMOperation

An FCMOperation defines the interface to an FCMNode, including its signature. An example specialization of FCMOperation is a WSDL (Web Services Definition Language) Operation, which defines an optional input message, an optional output message and optional fault messages.

5.6.6 FCMParameter

FCMParameters identify the signature of an FCMOperation, which can include inputs, outputs and faults. For a WSDL Operation, an FCMParameter provides the abstract definition of a message. FCMParameter has an association to TDLangElement, which provides the linkage to the language specific and physical representations of the data that an FCMParameter represents.

5.6.7 FCMCommand

An FCMCommand is a special kind of FCMNode that represents the invocation of a particular FCMOperation on an FCMComponent. An FCMCommand can be thought of as being analogous to a programming language statement that invokes a method on an object.
5.6.8 FCMFunction

An FCMFunction is a special kind of FCMNode. It’s similar to an FCMCommand in that it represents the invocation of a particular FCMOperation. However, in this case the FCMOperation does not have an FCMComponent associated with it. An FCMFunction can be thought of as being analogous to a programming language statement that makes a procedural call or invokes a transaction.

5.6.9 FCTerminal

FCTerminals provide a mechanism for identifying the interfaces to an FCMNode. They are derived, with the derivation based on the type of FCMNode they are associated with. For example, an FCMNode that represents the invocation of a WSDL operation will have FCTerminals that are derived one for one from the parameters of the operation. An FCMMappingNode (in the FCM package) will have one input terminal for each piece of input data, and one output terminal for each output (typically one, formed by combining the inputs in some way). FCMJoinNodes and FCMBranchNodes (in the FCM package) have no terminals.

5.6.10 FCTerminalToNodeLink and FCTerminalToTerminalLink

These are abstract specializations of FCMConnection.

An FCTerminalToNodeLink represents an FCMConnection from a particular outcome of a source FCMNode to a target FCMNode. The “source” association identifies which outcome to use as the source of the FCTerminalToNodeLink. FCMControlLinks (in the FCM package) are concrete examples of FCTerminalToNodeLinks.

FCTerminalToTerminalLink is a specialization of FCTerminalToNodeLink that in addition specifies the particular input of the target FCMNode to connect to. This is identified by the “target” association. FCMDataLinks (in the FCM package) are concrete examples of FCTerminalToTerminalLinks.

5.6.11 FCMAnnotation

An important design goal of the Flow Composition Model is the ability to be able to work with FCMComponents of pre-defined types that were not designed with the specific needs of the Flow Composition Model in mind. This means that the Flow Composition Model cannot require FCMComponents to support special attributes or behaviors in order to participate in Flow Compositions. In order to satisfy this requirement, the Flow Composition Model allows an FCMAnnotation object to be associated with each FCMComponent. An FCMAnnotation is an object that is used to carry information about an FCMComponent that is useful or necessary in the context of a Flow, but which is not a property of the FCMComponent itself. A common example is that every FCMComponent must have a name associated with it to identify it within the FCMComposition, even though not all FCMComponents have a name property.
5.6.12 FCMSource and FCMSink

FCMSources and FCMSinks are special FCMNodes that are used to define the FCMOperations available on the public interface that can be derived from an FCMComposition. An FCMSource represents an entry point into the behaviors defined by an FCMComposition. An FCMSource within an FCMComposition corresponds to a One-way or Request-Response operation defined on the external interface defined by the FCMComposition. An FCMSource can act only as a sourceNode for an FCMConnection. The source FCMTerminal for the FCMConnection is derived from the input FCMParameter of the FCMOperation that the FCMSource implements.

An FCMSource may have associated with it a corresponding FCMSink. An FCMSink is an FCMNode that defines the output and fault FCMParameters of the FCMOperation associated with an FCMSource. An FCMSink can act only as a targetNode for an FCMConnection; the target FCMTerminal for the FCMConnection is derived from the output or fault FCMParameters of the FCMOperation.

5.6.13 FCMCompositionBinding

An FCMComponent can be implemented as an FCMComposition. In this case, the FCMSources and FCMSinks of the FCMComposition define the external operations that are derived from the FCMComposition. FCMCompositionBinding provides the mechanism for linking an FCMComponent to its implementation as an FCMComposition. This is how hierarchical composition – the ability to use flow compositions to create new flow compositions – is achieved.

5.6.14 TDLangElement

TDLangElement is a class in the Common Application Metamodel, which is part of the Enterprise Application Integration submission due to finalize in August. It is used in the model to tie FCMParameter into the data typing and type composition structure that the metamodel provides.

5.6.15 FCMType

An FCMType can be thought of as analogous to the definition of a Java or C++ class, in the sense that it defines the interface (operations and their inputs, outputs, and faults) for a type that can be instantiated. An FCMComponent is an instance of an FCMType. FCMTypes can be created based on FCMCompositions; in this case, the FCMComposition defines the implementation of the FCMType. FCMTypes can also be types created outside of the flow composition domain, enabling instances of outside types to be incorporated as FCMComponents in compositions.
5.7 FCM Package

The FCM package provides a set of specializations of the FCMCore package. The FCM package consists largely of definitions of particular subtypes of FCMNode and FCMConnection that are designed to provide a common set of design abstractions across a variety of flow model types used in, e.g., message brokering, workflow or application component scripting.

The FCM package is described using two diagrams:

- Figure 5-16 – FCMConnections diagram.
- Figure 5-17 on page 5-39 – FCMNodes diagram.

![Figure 5-16 FCM Package, FCMConnections Diagram](image-url)
5.7.1 FCMControlLink

An FCMControlLink is an FCMConnection between FCMNodes that controls the sequencing of execution of the FCMNodes. An FCMControlLink is activated when its source FCMNode is completed and it defines a trigger for activation of the target FCMNode of the link.

5.7.2 FCMDataLink

An FCMDataLink is an FCMConnection that specifies the flow of data between FCMNodes.

5.7.3 FCMDecisionNode

An FCMDecisionNode is an FCMNode used to determine control flow based on a set of Boolean expressions; essentially it represents a ‘switch’ in the control flow. A DecisionNode has one input and two or more outputs that represent the ‘cases’ of the switch. Each output is associated with a Boolean expression. The representation of a decision node in a flow diagram is shown below.
The little diamond on its side represents an FCMDecisionNode and a control connection from the output of the icon on the left to the input of the FCMDecisionNode.

5.7.4 FCMConditionalControlLink

An FCMConditionalControlLink offers an alternative design to the use of an FCMDecisionNode. In this design, a Boolean expression is associated with the FCMConditionalControlLink, removing the need for a separate FCMDecisionNode.

5.7.5 FCMJoinNode

An FCMJoinNode is a specialized FCMNode used to force the synchronization of control flow. An FCMJoinNode has two inputs and one output. Because the usage of a decision node is very common, there is a specialized visual representation for an FCMJoinNode, as shown below. In flow diagram notation, the little T on its side represents an FCMJoinNode and a control connection from the output of the FCMJoinNode to the input of the FCMDecisionNode on the right.

5.7.6 FCMJoinCommand

An FCMJoinCommand is an alternative to an FCMJoinNode. It has a Boolean expression associated with it, removing the need for a separate FCMJoinNode.

5.7.7 FCMMappingNode
An FCMMappingNode is a specialized FCMNode used to specify a transformation of input message formats to an output message format. Because the usage of an FCMMappingNode is very common, FCMMappingNodes have a special graphical representation, as shown. In flow diagram notation, the circle with the cross represents the FCMMappingNode.

5.7.8 FCMMappingDataLink

An FCMMappingDataLink is an alternative design to the use of an FCMMappingNode. In this design, a mapping is associated with the link removing the need for a separate FCMMappingNode.

5.7.9 FCMMapping

An FCMMapping is an object that specifies a transformation of one message format into another.

5.7.10 FCMCondition

FCMConditions are the boolean expressions used by FCMDcisionNodes and FCMConditionalControlLinks to determine control flow.

5.7.11 FCMBranchNode

An FCMBranchNode provides a way to branch control flow in one or more directions. An FCMBranchNode can specify that all of its outbound connections are given control, or only one (based on a condition) is given control.

5.8 FCM Profile

Table 5-2 summarizes the UML Profile for the FCM.

5.9 Example

Figure 5-18 is the graphical representation of an FCMComposition to transfer and refund money.
The FCMComponents that define the objects within the FCMComposition are checkingAccount and riskAssessor. checkingAccount is an instance of Account; riskAssessor is an instance of RiskAssessor.

The FCMComposition has two points of entry into it: TransferSource and RefundSource, each providing a different behavior. To an external user, the FCMComposition simply provides the two operations of transferring or refunding money. The internal composition of the flow is implementation detail that the external user does not need to be aware of.

An FCMComposition defines the flow of control (FCMControlLinks) and the flow of data (FCMDataLinks) between FCMNodes. The solid lines in the flow diagram represent FCMControlLinks, and the dot-dash lines represent FCMDataLinks. Both are specialized FCMConnections.

The dotted lines in the flow diagram identify the “performedBy” relationship between FCMCommands and FCMComponents.
The rest of this example looks at the transfer money path through the flow.

![Diagram of transfer money flow](image)

**Figure 5-19**  FCMSource and FCMSink for the Transfer Money FCMFlow

**TransferSource**, an FCMSource, acts as a public entry point into the composition. It defines the input for the operation of transferring money from an account, such as an account number and the amount to be transferred. **TransferSink** is the corresponding FCMSink and defines the results of the operation. A composition can have more than one FCMSource, each acting as another public entry point into it.

FCMSources and FCMSinks are specialized FCMNodes.

![Diagram of TransferSource to CheckAccount](image)

**Figure 5-20**  FCMControlLink and FCMDataLink from TransferSource to CheckAccount

**SendMoney** and **ReturnMoney** are both FCMFunctions – FCMNodes that do not have associated FCMComponents. They represent procedural or transaction logic that does not involve interacting with any FCMComponents in the composition.
An FCMControlLink (solid line) connects the TransferSource node to the **CheckAccount** node. TransferSource is the sourceNode for the connection and CheckAccount is the targetNode. This connection triggers the activation of CheckAccount.

An FCMDataLink (dotted arrow) also connects the TransferSource node to the CheckAccount node. This indicates that data, as well as execution control, flow between these two nodes. The data that flows is **TransferMoneyData**. This is the signature (input FCMPParameter) of the operation that TransferSource implements. The interface defined by the source FCMTerminal for the connection is derived from it.

**CheckAccount**, **AssessRisk**, and **DebitAccount**, are all FCMCommands, a kind of specialized FCMNode. Each represents the invocation of a particular FCMOperation on an FCMComponent. For example, CheckAccount represents the invocation of **checkingAccount’s getBalance** operation.

![Diagram](image)

**Figure 5-21** FCMCommand with associated FCMConnections and FCMComponent

CheckAccount has an FCMTerminal for the inbound FCMDataLink. The data flowing across the FCMDataLink is TransferMoneyData. This FCMTerminal defines the input interface to CheckAccount and is derived from getBalance’s input FCMPParameter. CheckAccount also has an FCMTerminal representing a successful outcome from its execution. This FCMTerminal acts as the source for the FCMControlLink to the FCMDecisionNode that follows it. It is also the source for the FCMDataLink that connects to FCMCommand DebitAccount.
The diamond in the flow diagram represents an FCMDecisionNode. In this example, the FCMDecisionNode has a single Boolean expression associated with it (if balance > amount). The value of the expression determines whether control flows to DebitAccount or to AssessRisk. FCMDecisionNodes can have a more complex case structure with control flowing to a different FCMNode for each case.

Other kinds of FCMNodes can have multiple outbound control flows as well. FCMCommand AssessRisk has one inbound and two outbound FCMTerminals:

- The inbound FCMTerminal represents the input to the associated doAssessment operation.
- The white outbound FCMTerminal represents a successful result, and transfers control to DebitAccount.
- The dark outbound FCMTerminal represents an exception (“bad risk”), and transfers control to TransferSink to end the flow.

If doAssessment had other types of exceptions (for instance “credit history not found”), AssessRisk would have other outbound FCMTerminals to support them.

Hierarchical composition – the ability to use flow compositions to create new flow compositions – is a key feature of the Flow Composition Model. In this example, FCMComponent riskAssessor could be bound to a previously defined FCMComposition as its implementation. Similarly, through the same binding mechanism, the entire TransferMoney FCMComposition could be bound as the implementation of an FCMComponent in a more complex Billing flow.

Section I - Introduction

This chapter describes a mapping between the Unified Modeling Language (UML) and the Metaobject Facility (MOF). The two-way mapping supports both designing metamodels with UML (UML to MOF) and viewing metamodels with UML (MOF to UML). The sections in this chapter provide a table showing the mapping of element types, detailed mapping descriptions for individual element types, and guidelines for designing metamodels using UML.

The mapping is a UML profile. Per the definition of a UML profile, this chapter contains the following information.

<table>
<thead>
<tr>
<th>UML Profile Requirements</th>
<th>Where Requirements are Satisfied in this Chapter</th>
</tr>
</thead>
<tbody>
<tr>
<td>UML metamodel elements supported by the profile</td>
<td>All metamodel elements are listed in the UML-to-MOF Mapping Table below</td>
</tr>
<tr>
<td>Features defined by the profile as new metamodel elements</td>
<td>This profile defines no new metamodel elements</td>
</tr>
<tr>
<td>Common model elements predefined by the profile</td>
<td>Stereotypes are listed in the UML-to-MOF Mapping Table below. There are no other predefined elements</td>
</tr>
<tr>
<td>Features defined by the profile using standard extension mechanisms</td>
<td>UML stereotypes are listed in the UML-to-MOF Mapping Table below. A mapping section for each element type includes a subsection identifying UML tags used by the profile.</td>
</tr>
<tr>
<td>Natural language prose that informally defines the semantics of the profile</td>
<td>The body of this chapter explains the UML-to-MOF mapping — separate sections explain each element type</td>
</tr>
<tr>
<td>Well-formedness rules that formally define the semantics of the profile</td>
<td>A mapping section for each element type below includes a subsection expressing precisely how properties are mapped and a subsection listing constraints</td>
</tr>
</tbody>
</table>
The profile has limitations. Some MOF details cannot be rendered in UML using this profile. The mapping section for each element type includes a subsection listing specific limitations.

Section II - UML-to-MOF Mapping Table

The following UML elements and stereotypes are supported by the profile. Each maps to a specific MOF element as shown in the table below.

<table>
<thead>
<tr>
<th>UML Element</th>
<th>Stereotype</th>
<th>MOF Element</th>

Section III - Mapping Details

The profile applies to an entire UML Model stereotyped as a <<metamodel>>. The profile applies to all elements contained directly or indirectly by the Model through composite associations. Hence, stereotypes are not generally needed for contained elements. All contained elements must be supported by the profile.

Separate sections below explain the mappings for each element type. Each section contains subsections covering these topics: tags, mapping properties, constraints, and limitations.

Tags are used for MOF properties not directly supported by UML. Except for the standard UML tag “documentation,” all tags used by the profile are prefixed with “org.omg.uml2mof” to mark them as belonging to this profile. All tags are optional unless specified as required.
6.1 ModelElement

In both UML and MOF, ModelElement is an abstract class. General tags and constraints on ModelElements are described below. The property map described below applies to the general cases where a UML ModelElement maps to a MOF ModelElement. In some cases the general map for a property is overridden for specific subclasses of MOF ModelElement.

6.1.1 Tags on UML ModelElement

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>documentation</td>
<td>an annotation for the ModelElement</td>
</tr>
</tbody>
</table>

6.1.2 ModelElement Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
</tr>
<tr>
<td>annotation</td>
<td>value of taggedValue with tag = “documentation”; otherwise “”</td>
</tr>
<tr>
<td>container</td>
<td>namespace</td>
</tr>
<tr>
<td>constraints</td>
<td>constraint</td>
</tr>
</tbody>
</table>

6.1.3 ModelElement Constraints

All constraints imposed by the MOF Specification are implicitly imposed based on the mapping to MOF defined herein.

Every UML ModelElement that maps to an MOF ModelElement must have a name.

6.1.4 ModelElement Limitations

None.

6.2 Package

A UML Model stereotyped as a <<metamodel>> maps to a MOF Package. Within a UML Model that maps to a MOF Package, any nested Model also maps to a MOF Package.
6.2.1 Tags on UML Model with Stereotype <<metamodel>>

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.clusteredImport</td>
<td>Comma-separated list of names of MOF Import objects that are clustered.</td>
</tr>
<tr>
<td>org.omg.uml2mof.hasImplicitReferences</td>
<td>“false” to prevent MOF References from being implied by AssociationEnds; “true” or no tag to imply a MOF Reference for each navigable AssociationEnd whose association and opposite end's type are owned by the same package.</td>
</tr>
</tbody>
</table>

6.2.2 Model-to-Package Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>If namespace is a UML Model that is mapped to a MOF Package by this profile, then the package. If namespace is null or is not mapped to a MOF Package, then null.</td>
</tr>
<tr>
<td>contents</td>
<td>ownedElement, taggedValue*</td>
</tr>
<tr>
<td>isAbstract</td>
<td>isAbstract</td>
</tr>
<tr>
<td>isRoot</td>
<td>isRoot</td>
</tr>
<tr>
<td>isLeaf</td>
<td>isLeaf</td>
</tr>
<tr>
<td>supertypes</td>
<td>generalization.parent</td>
</tr>
</tbody>
</table>

* See section on MOF Tag about which tags are mapped to MOF Package contents

6.2.3 Model-to-Package Constraints

All UML elements contained by the Model through composite associations transitively are limited to the types and stereotypes named in this profile.

All constraints imposed by the MOF Specification are implicitly imposed, based on the mapping to MOF defined herein, on the UML Model and all of its contents.

All names listed for a tag of “org.omg.uml2mof.clusteredImport” must match names of MOF Import objects in the contents of the MOF Package.

A UML Model representing a nested MOF Package must not have a tag of “org.omg.uml2mof.hasImplicitReferences”.

UML ownedElement must be ordered.

UML taggedValue must be ordered.

6.2.4 Model-to-Package Limitations

The order of MOF Package.contents are not fully preserved when rendered using the profile because UML has separate associations for ownedElement and taggedValue.
6.3 Import

A UML ElementImport maps directly to a MOF Import.

6.3.1 Tags on UML ElementImport

None. Tags are not supported because UML ElementImport is not a ModelElement.

6.3.2 ElementImport-to-Import Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>alias if given, otherwise importedElement.name</td>
</tr>
<tr>
<td>annotation</td>
<td>none</td>
</tr>
<tr>
<td>container</td>
<td>package</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>isClustered</td>
<td>If package has a taggedValue with tag = “org.omg.uml2mof.clusteredImport” and the value includes the name of the MOF Import, then true; otherwise false</td>
</tr>
<tr>
<td>imported</td>
<td>importedElement</td>
</tr>
</tbody>
</table>

6.3.3 ElementImport-to-Import Constraints

The importedElement must be either a UML Model stereotyped as a <<metamodel>> or a Class owned directly or indirectly within such a Model.

6.3.4 ElementImport-to-Import Limitations

The profile does not support annotation of an Import.

6.4 Class

A UML Class maps directly to a MOF Class.

6.4.1 Tags on UML Class

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.isSingleton</td>
<td>“true” or “false” indicating a value for isSingleton</td>
</tr>
</tbody>
</table>
6.4.2 Class Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>contents</td>
<td>ownedElement followed by feature (in order)</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>isAbstract</td>
<td>isAbstract</td>
</tr>
<tr>
<td>isRoot</td>
<td>isRoot</td>
</tr>
<tr>
<td>isLeaf</td>
<td>isLeaf</td>
</tr>
<tr>
<td>supertypes</td>
<td>generalization.parent</td>
</tr>
<tr>
<td>isSingleton</td>
<td>value of taggedValue with tag = &quot;org.omg.uml2mof.isSingleton&quot;; otherwise false</td>
</tr>
</tbody>
</table>

6.4.3 Class Constraints

UML ownedElement must be ordered.

6.4.4 Class Limitations

The order of MOF Class.contents are not fully preserved when rendered using the profile because UML has separate associations for ownedElement and feature.

6.5 Attribute

A UML Attribute with no stereotype maps to a MOF Attribute.

6.5.1 Tags on UML Attribute with No Stereotype

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.isUnique</td>
<td>“true” or “false” indicating a value for isUnique</td>
</tr>
<tr>
<td>org.omg.uml2mof.isOrdered</td>
<td>“true” or “false” indicating a value for isOrdered</td>
</tr>
<tr>
<td>org.omg.uml2mof.isDerived</td>
<td>“true” or “false” indicating a value for isDerived</td>
</tr>
</tbody>
</table>
6.5.2 Attribute Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>owner</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>scope</td>
<td>ownerScope</td>
</tr>
<tr>
<td>type</td>
<td>type</td>
</tr>
<tr>
<td>multiplicity</td>
<td>multiplicity.range; isUnique and isOrdered are false unless specified with tags shown above</td>
</tr>
<tr>
<td>isChangeable</td>
<td>changeability = changeable</td>
</tr>
<tr>
<td>isDerived</td>
<td>value of taggedValue with tag = “org.omg.uml2mof.isDerived”; otherwise false</td>
</tr>
</tbody>
</table>

6.5.3 Attribute Constraints

UML changeability must be either changeable or frozen.

UML multiplicity must have a single range.

6.5.4 Attribute Limitations

None.

6.6 Reference

A UML Attribute stereotyped as a <<reference>> maps to a MOF Reference.

Also, if the UML Model representing the outermost containing MOF Package does not have a tag of “org.omg.uml2mof.hasImplicitReferences” with a value of “false”, then a MOF Reference is implied by each eligible UML AssociationEnd. An end is considered eligible if it is navigable, there is no explicit MOF Reference for that end within the same outermost MOF Package, and the end’s association is owned by the same package that owns its opposite end’s type (so as to not create circular package dependencies).
6.6.1 Tags on UML Attribute with Stereotype \<<reference>>

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.referencedEnd</td>
<td>the name of an opposite AssociationEnd which is the referencedEnd</td>
</tr>
</tbody>
</table>

6.6.2 Explicit Reference Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>owner</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>scope</td>
<td>ownerScope</td>
</tr>
<tr>
<td>type</td>
<td>type</td>
</tr>
<tr>
<td>multiplicity</td>
<td>multiplicity.range; isUnique and isOrdered are taken from the referencedEnd</td>
</tr>
<tr>
<td>isChangeable</td>
<td>changeability = changeable</td>
</tr>
<tr>
<td>referencedEnd</td>
<td>the one AssociationEnd of owner.allOppositeAssociationEnds which is identified by a taggedValue on the UML Attribute with tag = “org.omg.uml2mof.referencedEnd”, or lacking a taggedValue, the UML Attribute’s name</td>
</tr>
</tbody>
</table>

6.6.3 Implicit Reference Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>referencedEnd’s name</td>
</tr>
<tr>
<td>annotation</td>
<td>&quot;&quot;</td>
</tr>
<tr>
<td>container</td>
<td>the type of the AssociationEnd opposite to the referencedEnd</td>
</tr>
<tr>
<td>constraints</td>
<td>none</td>
</tr>
<tr>
<td>visibility</td>
<td>referencedEnd’s visibility</td>
</tr>
<tr>
<td>scope</td>
<td>instance_level</td>
</tr>
<tr>
<td>type</td>
<td>referencedEnd’s type</td>
</tr>
<tr>
<td>multiplicity</td>
<td>referencedEnd’s multiplicity</td>
</tr>
<tr>
<td>isChangeable</td>
<td>referencedEnd’s isChangeable</td>
</tr>
<tr>
<td>referencedEnd</td>
<td>the AssociationEnd that implies the Reference</td>
</tr>
</tbody>
</table>

6.6.4 Reference Constraints

UML changeability must be either changeable or frozen.

UML multiplicity must have a single range.
For a UML Attribute with a <<reference>> stereotype, if there is a UML taggedValue with tag = “org.omg.uml2mof.referencedEnd”, it must identify a visible AssociationEnd from among the Attribute’s owner.allOppositeAssociationEnds. If no such taggedValue is present, the UML Attribute name must identify a visible AssociationEnd from among the Attribute’s owner.allOppositeAssociationEnds.

For a UML Attribute with a <<reference>> stereotype, if the Attribute’s name is also the name of an AssociationEnd from among the Attribute’s owner.allOppositeAssociationEnds, then the Attribute makes explicit the pseudo-attribute implied by the name of the AssociationEnd. The Attribute’s name does not conflict with the pseudo-attribute name. Rather, the Attribute makes the pseudo-attribute explicit in the class. In this case, the Attribute must not have a taggedValue identifying a different AssociationEnd than the one identified by the Attribute’s name.

### 6.6.5 Reference Limitations

None.

### 6.7 Operation

A UML Operation maps to a MOF Operation.

#### 6.7.1 Tags on UML Operation

None.

#### 6.7.2 Operation Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>owner</td>
</tr>
<tr>
<td>contents</td>
<td>parameter</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>scope</td>
<td>ownerScope</td>
</tr>
<tr>
<td>isQuery</td>
<td>isQuery</td>
</tr>
<tr>
<td>exceptions</td>
<td>raisedSignal</td>
</tr>
</tbody>
</table>

#### 6.7.3 Operation Constraints

UML raisedSignal must be ordered.

Each UML raisedSignal must be an Exception mapped by the profile.

#### 6.7.4 Operation Limitations

Unlike a MOF Operation, a UML Operation cannot contain a Constraint. Therefore the profile does not support an Operation containing a Constraint.
6.8 Parameter

A UML Parameter maps to a MOF Parameter.

6.8.1 Tags on UML Parameter

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.multiplicity</td>
<td>a multiplicity range such as “0..1”, “<em>” or “1..</em>”</td>
</tr>
<tr>
<td>org.omg.uml2mof.isOrdered</td>
<td>“true” or “false” indicating a value for isOrdered</td>
</tr>
<tr>
<td>org.omg.uml2mof.isUnique</td>
<td>“true” or “false” indicating a value for isUnique</td>
</tr>
</tbody>
</table>

6.8.2 Parameter Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>behavioralFeature</td>
</tr>
<tr>
<td>type</td>
<td>type</td>
</tr>
<tr>
<td>direction</td>
<td>kind</td>
</tr>
<tr>
<td>multiplicity</td>
<td>lower and upper are 1, and isOrdered and isUnique are false, unless specified with tags shown above</td>
</tr>
</tbody>
</table>

6.8.3 Parameter Constraints

UML changeability must be either changeable or frozen.

A multiplicity specified by a taggedValue with tag = “org.omg.uml2mof.multiplicity” must represent a single valid multiplicity range.

6.8.4 Parameter Limitations

None.

6.9 Exception

A UML Exception maps to a MOF Exception. A UML Exception is a Signal, which is a Classifier, whereas MOF Exception is BehavioralFeature. For this reason, UML Attributes of an Exception, rather than UML Parameters, represent MOF Exception Parameters in the profile.

6.9.1 Tags on UML Exception

None.
6.9.2 Exception Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>contents</td>
<td>feature</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>scope</td>
<td>classifier</td>
</tr>
</tbody>
</table>

6.9.3 Exception Constraints

Each feature of the UML Exception must be an Attribute.

6.9.4 Exception Limitations

The profile does not support an Exception having instance-level scope.

6.10 Exception Parameter

An Attribute of a UML Exception maps to a Parameter of a MOF Exception.

6.10.1 Tags on Attribute of UML Exception

```
<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.isOrdered</td>
<td>“true” or “false” indicating a value for isOrdered</td>
</tr>
<tr>
<td>org.omg.uml2mof.isUnique</td>
<td>“true” or “false” indicating a value for isUnique</td>
</tr>
</tbody>
</table>
```

6.10.2 Attribute-to-Parameter Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>owner</td>
</tr>
<tr>
<td>type</td>
<td>type</td>
</tr>
<tr>
<td>direction</td>
<td>out</td>
</tr>
<tr>
<td>multiplicity</td>
<td>multiplicity.range; isOrdered and isUnique are false unless specified with tags shown above</td>
</tr>
</tbody>
</table>

6.10.3 Attribute-to-Parameter Constraints

None.

6.10.4 Attribute-to-Parameter Limitations

None.
6.11 Association

A UML Association maps directly to a MOF Association.

A UML Association stereotyped as <<implicit>> is ignored by the profile and is not mapped to a MOF Association.

6.11.1 Tags on UML Association

None.

6.11.2 Association Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>contents</td>
<td>ownedElement, connection</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>isAbstract</td>
<td>isAbstract</td>
</tr>
<tr>
<td>isRoot</td>
<td>isRoot</td>
</tr>
<tr>
<td>isLeaf</td>
<td>isLeaf</td>
</tr>
<tr>
<td>supertypes</td>
<td>generalization.parent</td>
</tr>
</tbody>
</table>

6.11.3 Association Constraints

An Association must have exactly two ends.

6.11.4 Association Limitations

The order of MOF Class.contents are not fully preserved when rendered using the profile because UML has separate associations for ownedElement and connection.

6.12 AssociationEnd

A UML AssociationEnd maps directly to a MOF AssociationEnd.

6.12.1 Tags on UML AssociationEnd

None.
6.12.2 AssociationEnd Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>container</td>
<td>association</td>
</tr>
<tr>
<td>type</td>
<td>type</td>
</tr>
<tr>
<td>multiplicity</td>
<td>multiplicity.range, isUnique maps to upper &gt; 1, isOrdered maps to ordering = ordered</td>
</tr>
<tr>
<td>aggregation</td>
<td>aggregation (UML aggregate matches MOF shared)</td>
</tr>
<tr>
<td>isNavigable</td>
<td>isNavigable</td>
</tr>
<tr>
<td>isChangeable</td>
<td>changeability = changeable</td>
</tr>
</tbody>
</table>

6.12.3 AssociationEnd Constraints

An Association must have exactly two ends.

UML changeability must be either changeable or frozen.

UML multiplicity must have a single range.

6.12.4 AssociationEnd Limitations

None.

6.13 DataType

A UML DataType maps directly to a MOF DataType.
### 6.13.1 Tags on UML DataType

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.corbaType</td>
<td>CORBA IDL type name or type declaration</td>
</tr>
<tr>
<td>org.omg.uml2mof.repositoryId</td>
<td>A repository id applicable within a typeCode constructed from a CORBA IDL type declaration</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>contents</td>
<td>TypeAlias objects as required by taggedValue with tag = &quot;org.omg.uml2mof.corbaType&quot;*; otherwise, a typeCode based on name**</td>
</tr>
<tr>
<td>visibility</td>
<td>visibility</td>
</tr>
<tr>
<td>isAbstract</td>
<td>isAbstract</td>
</tr>
<tr>
<td>isRoot</td>
<td>isRoot</td>
</tr>
<tr>
<td>isLeaf</td>
<td>isLeaf</td>
</tr>
<tr>
<td>supertypes</td>
<td>generalization.parent</td>
</tr>
<tr>
<td>typeCode</td>
<td>value of taggedValue with tag = &quot;org.omg.uml2mof.corbaType&quot;*; otherwise, a typeCode based on name**</td>
</tr>
</tbody>
</table>

* If a TaggedValue specifies a CORBA type, the value is parsed to determine the typeCode. If the value simply names a type, then it must name a CORBA primitive type. Otherwise, the value must be an IDL type declaration. Wherever the declaration refers by name to a Classifier contained in or imported into the metamodel, a MOF TypeAlias is constructed to reference the named Classifier. If there is a taggedValue with tag = \"org.omg.uml2mof.corbaType\", then its value is used wherever a repository id can be specified within the typeCode.

** If a TaggedValue does not specify a CORBA type, then a CORBA type is determined from the name. The name matching is case-insensitive. If the name matches the name of a standard CORBA type, then that type is used. All other names revert to a typedef for the CORBA string type.

### 6.13.2 DataType Property Map

### 6.13.3 DataType Constraints

The value of a taggedValue with tag = \"org.omg.uml2mof.corbaType\" must identify a valid CORBA type.

UML ownedElement must be ordered.

### 6.13.4 DataType Limitations

A CORBA typecode contains information which is not revealed in an IDL rendering of a type. Such information is not handled by the profile.

The order of MOF DataType.contents are not fully preserved when rendered using the profile because TypeAlias objects are listed via a taggedValue separately from UML ownedElement.
6.14 Constant

A UML DataValue maps to a MOF Constant.

6.14.1 Tags on UML DataValue

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.constantValue</td>
<td>the value of the constant</td>
</tr>
</tbody>
</table>

6.14.2 DataValue-to-Constant Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>classifier</td>
</tr>
<tr>
<td>value</td>
<td>value of taggedValue with tag = “org.omg.uml2mof.constantValue”</td>
</tr>
</tbody>
</table>

6.14.3 DataValue-to-Constant Constraints

A taggedValue is required to provide the Constant value. The value of the taggedValue must be a string representation of a valid value for the Constant’s type.

6.14.4 DataValue-to-Constant Limitations

None.

6.15 Constraint

A UML Constraint maps directly to a MOF Constraint.

6.15.1 Tags on UML Constraint

<table>
<thead>
<tr>
<th>Tag</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.omg.uml2mof.evaluationPolicy</td>
<td>“immediate” or “deferred” indicating a value for evaluationPolicy</td>
</tr>
</tbody>
</table>
6.15.2 Constraint Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>body.body</td>
</tr>
<tr>
<td>language</td>
<td>body.language</td>
</tr>
<tr>
<td>evaluationPolicy</td>
<td>value from taggedValue with tag = &quot;org.omg.uml2mof.evaluationPolicy&quot;; otherwise deferred</td>
</tr>
<tr>
<td>constrainedElement</td>
<td>constrainedElement</td>
</tr>
</tbody>
</table>

6.15.3 Constraint Constraints

None.

6.15.4 Constraint Limitations

A MOF Constraint’s expression has any type, but a UML Constraint’s expression body has string type. Therefore, the profile can support only an expression rendered as a string.

6.16 Generalizes

A UML Generalization maps to a MOF Generalizes link.

6.16.1 Tags on UML Generalization

None.

6.16.2 Generalization-to-Generalizes Property Map

None. Generalizes is an association, not a class.

6.16.3 Generalization-to-Generalizes Constraints

Each UML Generalization within a Model mapped to a MOF Package must connect GeneralizableElements that are also mapped to MOF elements.

6.16.4 Generalization-to-Generalizes Limitations

None.

6.17 Tag

A UML TaggedValue maps to a MOF Tag, except that any UML TaggedValue whose tag is used by this profile is not preserved as a MOF Tag.
6.17.1 Tags on UML TaggedValue

None. A UML TaggedValue cannot be tagged.

6.17.2 TaggedValue-to-Tag Property Map

<table>
<thead>
<tr>
<th>MOF Property</th>
<th>UML Property or Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>modelElement.name* + &quot;.&quot; + tag</td>
</tr>
<tr>
<td>annotation</td>
<td>&quot;&quot;</td>
</tr>
<tr>
<td>container</td>
<td>If modelElement is a Model then that Model, otherwise the Model that most immediately owns modelElement</td>
</tr>
<tr>
<td>constraints</td>
<td>none</td>
</tr>
<tr>
<td>tagId</td>
<td>tag</td>
</tr>
<tr>
<td>values</td>
<td>value</td>
</tr>
<tr>
<td>elements</td>
<td>modelElement</td>
</tr>
</tbody>
</table>

* if the modelElement is not a Model, then the name is qualified up to but not including the Model that most immediately owns the modelElement — each name is separated by a period (".") character.

6.17.3 TaggedValue-to-Tag Constraints

None.

6.17.4 TaggedValue-to-Tag Limitations

MOF allows a Tag to be contained by an object other than the one it tags. UML requires a tag to be contained by the object it tags. Therefore, when a MOF Tag is rendered in UML, the profile does not retain the relationship to the Tag’s container.

UML does not give a name to a TaggedValue other than its tag. Therefore, a MOF Tag name is not preserved when rendered in UML using the profile.

MOF supports any type of value for a Tag. UML supports only a string value. Therefore, the profile supports only string values.

MOF supports having multiple values with a single tag. UML supports only one. Therefore, the profile supports only a single value.

A single MOF tag can be attached to multiple model elements. A UML TaggedValue can be attached to only one. Therefore, the profile supports only a single ModelElement attached to a tag.

The profile does not support annotations, constraints or tags on tags.
Section IV - Guidelines

This section gives guidelines for designing metamodels using the UML profile for MOF. These guidelines are drawn from several experiences of using UML to design and extend metamodels deployed using MOF.

Refer to the MOF Specification for a comprehensive explanation of MOF.

6.18 Modularity

Separate different modeling areas into different metamodels. Minimize dependencies between metamodels. Make no circular dependencies between them — otherwise valid CORBA IDL interfaces cannot be generated.

The outermost package of a deployed metamodel can thought of as a type. It is the type of each MOF package extent defined by the metamodel. Avoid nesting metamodels as owned elements so that the metamodels can be deployed in various combinations rather than only as one enormous metamodel. A metamodel can import rather than own other metamodels. Importing gives the same organizational advantage as nesting without imposing strong composition. Metamodels can be imported in two ways: clustered and unclustered. If clustered, an imported metamodel is fully deployed within an extent of the importing metamodel, just as if the imported metamodel had been nested.

Use package inheritance to achieve polymorphism of package extents. If a MOF package inherits from a base package, then an extent of the package can be used wherever an extent of the base package can be used.

6.19 Associations

Give meaningful names to associations, even if you do not display the names in diagrams. The association name is used to define interfaces to access and manage links.

Generally, put an association in the same package as one of its connected classes. If the connected classes are in separate packages, put the association in the most specific package.

When extending an existing model from the outside, feel free to make associations to classes in the existing model. But use existing associations wherever they are appropriate. If you want to draw an association between specific classes for the purpose of showing an existing association between superclasses, then stereotype the association as <<implicit>> so that it is ignored in the mapping to MOF.

MOF does not support association classes or associations having more than two connections. In any case where you would use such an association, model the conceptual association as a class using separate associations for each connection.
6.20 References

A MOF reference is like a derived attribute whose derivation is tied to an association. The values of a reference for an object are the objects linked to that object. Modifying reference values causes links to be added and/or deleted.

When designing a metamodel that extends another from the outside, define references only in the extending metamodel, not in the metamodel it extends.

The definition of a MOF reference affects how package extents contain links. In general, an association link and the objects it connects can all belong to different package extents. However, the MOF Specification defines the Reference Closure Rule which requires any link tied to a reference to be contained by the same package extent as the object having the reference. If an association has references on both ends, both linked objects and the link must all be contained in the same package extent. Before defining a reference, give thought to the Reference Closure Rule so that you do not mistakenly prevent links from interrelating objects across different package extents. Conversely, use a reference where you want to force links to be in the same package extent as the linked objects.

Here is an example. Suppose a metamodel has a class called GE and an association from GE to GE called Generalizes. One end is called supertype and the other is called subtype. Both ends are navigable. If a reference is on both ends, then a link can only connect GE objects within the same package extent. If a reference is only on the subtype end (referring to supertype) then a link must be in the same package extent as its subtype, but it can link to a supertype in the same or a different package extent.

6.21 DataTypes

Avoid defining a complex data type where a class can be used.

Avoid defining enumerations because they limit extensibility. There is no way to extend an enumeration type from an outside metamodel.

6.22 Names

Form multiword names by concatenating words with no intervening spaces, hyphens or underscores. For names of packages, classifiers, and associations upcase the first letter of each word. For names of features and association ends upcase the first letter of each word except for the first word in the name. Do not prefix all of the names in a package with the package name — the package name is already part of the fully qualified name.

Using spaces, punctuation or leading numerals in names can cause problems for middleware, programming language, and XML bindings.
